

**Negative growth regulatory role of
PTPN11/SHP2 in breast epithelial tumorigenesis**

A thesis
submitted in partial fulfillment of the requirements

of the degree of
Doctor of Philosophy

By

Madhumita Chakladar

Roll No. /ID: 20143312

**INDIAN INSTITUTE OF SCIENCE EDUCATION AND RESEARCH
(IISER), PUNE**

2020

Dedicated to my beloved uncle
Late Sri Susanta Chakladar

Certificate

Certified that the work incorporated in the thesis entitled “Negative growth regulatory role of *PTPN11*/*SHP2* in breast epithelial tumorigenesis” submitted by Madhumita Chakladar was carried out by the candidate, under my supervision. The work presented here or any part of it has not been included in any other thesis submitted previously for the award of any degree or diploma from any other university or institution.

(Supervisor)

Prof. L S Shashidhara

Date: 27-05-2020

Declaration

I declare that this written submission represents my ideas in my own words and where others' ideas have been included, I have adequately cited and referenced the original sources. I also declare that I have adhered to all principles of academic honesty and integrity and have not misrepresented or fabricated or falsified any idea/data/fact/source in my submission. I understand that violation of the above will be cause for disciplinary action by the Institute and can also evoke penal action from the sources which have thus not been properly cited or from whom proper permission has not been taken when needed.

Date: 27-05-2020

Madhumita Chakladar

Roll No. 20143312

Acknowledgment

I would like to extend my sincere gratitude to my Ph.D. supervisor, Prof. L S Shashidhara for supporting my work. He has been constant guidance showing me a path in every up and down of my research career. It is said Ph.D. is like the character development in itself and Shashi has been a father-like figure who has shaped my ideas, scientific aptitude, scientific temperament, and most importantly gave me freedom and confidence for completing my work. Even though I was initially skeptical, I am thankful to Shashi for introducing me to data science and even more for making me enjoy doing bioinformatics as much as I enjoyed mammalian cell culture work. It is he who taught me it's ok to make mistakes and have made me learn to enjoy troubleshooting to find answers rather than see mistakes as more tasks. His guidance urged me to think and to have honesty towards my work. Every discussion with him has been insightful and has helped me find answers to most of the scientific problems I dealt with during my doctoral journey.

I would also like to thank my collaborators Prof. Stephen Cohen, UCPH, Denmark, and Dr. T S Sridhar, SJRI, Bangalore for guiding me through my bioinformatics work and clinical work. The cell culture work was partially done in SJRI, Bangalore and I would like to extend my regards to Dr. Jyothi S Prabhu and Dr. Madhumathy G Nair for providing me with lab space, reagents, and protocols. I am thankful to Dr. Devaki Kelkar, PCCM/IISER, Pune for analysing the TCGA and METABRIC data with me and Dr. Madhura Kulkarni, PCCM/IISER, Pune providing me with the premade 48 hours pQCXIH virus used in this study for YAP1 overexpression and also thank them both for helping me with writing the thesis.

This work has been shaped over the last four years under the guidance of my RAC members at IISER Pune. I am thankful to Dr. Mayurika Lahiri for her guidance and her generosity in providing me with the MCF10A cell line used in this study. I would also like to thank Dr. Kundan Sengupta and Dr. Siddhesh Kamat for directing my project on the right path during my RACs. I am happy to be a part of the IISER Pune scientific community and for being nurtured under the open lab facility and learning to share ideas and resources.

I would express my gratefulness to Prof. Sanjeev Galande and Dr. Nagaraj Balasubramaniun for accommodating me with cell culture resources and facilities whenever needed without a delay.

Most importantly I would like to extend my appreciation to the IISER Pune Biomanager, IISER Pune microscopy facility, IISER Pune Flow cytometry facility, IISER Pune Perkin Elmer facility, and IISER Pune Bio-Administration for their co-operation and support.

I would like to express my joy in sharing the lab space with the most cordial lab mates, colleagues, and friends at IISER Pune. I would also take this opportunity to extend my love and gratefulness to my parents, Mr. Prasanta Chakladar and Mrs. Swapna Chakladar, my sister Ms. Moumita Chakladar and my husband Mr. Rajdip Thakur for being supportive and encouraging towards my research career.

I would also extend my sincere gratitude to my little daughter, Ridhima for being part of the doctoral journey in a special way. This little wonder has been my biggest positive influence during completion of this beautiful journey and have shared my work load of early morning experiments and late-night thesis writing.

Abstract

Drosophila model system has played a pivotal role in the identification of genes involved at all stages of tumorigenesis. An RNAi mediated screen of the *Drosophila* genome conducted in our laboratory identified putative negative regulators of growth in Epidermal Growth Factor Receptor (EGFR) and Yorkie (Yki) driven tumors. In this study, human orthologues of the RNAi mediated screen were subjected to detailed network analyses. Enrichment of the protein-protein interaction network among these putative growth regulators (in humans) identified major signaling pathways like the Hippo pathway and the mitogen-activated protein kinase (MAPK) signaling pathway to be involved in driving both EGFR and the Yes-associated protein 1 (YAP1) (a mammalian ortholog of Yki) mediated tumorigenesis. One of the identified negative growth regulators in the Yki screen but not a positive in the EGFR screen was corkscrew (Csw), a non-receptor protein tyrosine phosphatase. Tyrosine-protein phosphatase type 11 (*PTPN11*) encoding the Src Homology Phosphatase 2 (SHP2) protein is one of the closest human orthologs of Csw and it is reported to be a bonafide oncogene in EGFR driven neoplasia. However, our clinical metadata analysis showed *PTPN11*/SHP2 functions as a putative tumor suppressor in breast adenocarcinoma (BRCA). Our analysis of dataset availed by the Molecular Taxonomy of Breast cancer International Consortium (METABRIC), 2012 showed *PTPN11*/SHP2 copy number loss in Luminal A subtype of breast cancer patient correlated to poor 4 years disease-specific survival (DSS) and late-stage cancer at diagnosis. Furthermore, our analysis of The Cancer Genome Atlas (TCGA) BRCA level 4 protein data showed low expression levels of active phospho SHP2-Y542 associated with larger tumor size and more lymph node positivity in Luminal A subtype of patients at diagnosis.

We experimentally investigated the possible role of *PTPN11*/SHP2 as a tumor suppressor in breast cancer. Knockdown of *PTPN11*/SHP2 in MCF10A, a non-transformed breast epithelial cell line, showed increased migration and cell shape changes to mesenchymal morphology, although there was no change in the rate of cell proliferation. Besides, the treatment of *PTPN11*/SHP2 knockdown cells with epirubicin (chemotherapeutic drug) showed better survival and reduced apoptosis. However, we did not observe any change in the levels of Bcl associated X protein (BAX), a global pro-apoptotic molecule. *PTPN11*/SHP2 may interact with other apoptotic effectors, which needs to be further investigated.

In the context of YAP1 driven neoplasia, we analyzed the METABRIC dataset. Cohorts that had high levels of YAP1 and copy number loss of *PTPN11*/*SHP2* correlated to grade 3 tumors at diagnosis and poor 4 years DSS. We examined this relationship in YAP1 overexpressing MCF10A cells. Knockdown of *PTPN11*/*SHP2* in the background of over-expressed YAP1 did not change the proliferation rate, which was already at higher levels when wild type YAP1 alone was over-expressed. In summary, we conclude, the tumor suppressor role of *PTPN11*/*SHP2* in breast tumorigenesis may use a pathway independent of YAP1.

Molecules like *PTPN11*/*SHP2*, YAP1, and P53 among many others which show dual specificity in tumorigenesis in the same tissue depending on the upstream signaling cues present challenges in the field of targeted drug therapy. This study puts forth the importance of understanding the contexts and behavior of such dual molecules depending on upstream signaling cues to allow effective cancer treatment.

Chapter 1: Introduction

Organism's growth is a concerted action of multiple signaling pathways that maintain the balance of cellular proliferation and death. Yorkie (Yki), the primary effector of the hippo signaling kinase cascade, Warts (Wts), Salvador (Sav), and Hippo (Hpo), is involved in upregulating proliferation and inhibiting cell death, plays an important role in organism's growth (Ciriello et al. 2015)(D. Pan 2010) (Figure 1.1). Deregulation of signaling pathways either because of hyperactivation of growth promoters like the Yki, Epidermal Growth Factor Receptor (EGFR), and Phosphatidylinositol 3 kinase (PI3K) protein kinase B (AKT) or downregulation of negative growth regulators like P53 and Hpo often leads to tumor formation and neoplastic transformations (Hanahan and Weinberg 2011; Moroishi, Hansen, and Guan 2015).

Figure 1.1: Schematic representation of the Yki/Yes Associated Protein 1 (YAP1) pathway in *Drosophila* and humans. Hippo pathway is conserved from flies to humans and plays important role in controlling growth and proliferation processes. Image reproduced from D. Pan 2010.

Tumor development and cancer progression is a multistep process constituting ten major hallmarks. A tumor typically goes through uninhibited growth due to sustained proliferative signaling, decreased cell death, an increase in angiogenesis to support the growing tumor mass, epithelial to mesenchymal transformations, and metastasis, the final stage wherein tumor cells invade into neighbouring lymph nodes and organs (Hanahan and Weinberg 2011). During this process, the cells lose their cellular identity, become clonally populated, show intra-tumor heterogeneity, and adjacent stromal cells further help in tumor dissemination and metastatic colonization (Lambert et al., 2017). Progressive accumulation of mutations in these tumor cells including mutations in DNA repair genes leads to further genomic instability and neoplastic tumor growth (McGranahan and Swanton 2017; Tubbs and Nussenzweig 2017). Comprehensive sequencing of tumor samples has identified a total of 140 driver mutations, of which a minimum of two to a maximum of eight driver mutations are reported to be involved in the neoplastic transformation of solid tumors (Vogelstein et al. 2013).

Using a fly model system, co-operativity of growth regulatory pathways involving a minimum of two driver mutations allowed further understanding of the process of tumorigenesis and metastasis *in-vivo* (Miles, Dyson, and Walker 2011; Washburn and Washburn 2013). Oncogenic mutation of Ras^{v12} and loss of function of Scribbled, a known tumor suppressor, causes metastatic lesions in the eye antennal disc of *Drosophila* through paracrine Janus kinase (JNK) signaling (Wu, Pastor-Pareja, and Xu 2010). Furthermore, cooperative interaction has been reported between the Suppressor of cytokine signaling 36E (Socs36E) and EGFR to promote EGFR driven tumorigenesis through Bantam miRNA in the wing imaginal disc of *Drosophila* larvae (Herranz et al. 2012). A follow-up study to understand co-operativity in EGFR driven neoplasia, identified Perlecan expression in EGFR overexpressing epithelial cells and promotes the expansion of mesenchymal cells by upregulating Wnt signaling in epithelial cells and Bone Morphogenetic Proteins (BMP) signaling pathway in mesenchymal cells (Herranz, Weng, and Cohen 2014). Moreover, an RNAi mediated screen of the *Drosophila* genome conducted in our laboratory identified context-specific negative growth regulators in EGFR driven and Yki driven neoplasia (Groth et al. 2019). Phenotypic observation showed, oncogenic overexpression of Yki or EGFR gave a small overgrowth of the wing disc while RNAi mediated knockdown of genes in Yki/EGFR overexpressing discs that gave larger overgrowth of the wing disc, a giant larval phenotype, inhibited pupariation of the larvae and in some cases lead to metastatic lesions across the body of

larvae at least across two biological replicates were recorded as putative negative regulators of growth (referred to as positive candidates). The screen identified 74 and 905 fly genes whose depletion drives the neoplastic transformation of EGFR and Yki overexpressing wing imaginal discs of *Drosophila*. An independent screen in this study also identified 32 fly genes whose suppression limits EGFR overexpressing tumor growth in the SOCs RNAi background. This study includes the identification of orthologs of all positives from three independent RNAi mediated screen of the *Drosophila* genome and enlists the major pathways involved in EGFR and Yki/YAP1 driven neoplasia. The specificity of the screen and our analysis is reflected from the identification of tumor suppressors like p53 and Hpo and known growth regulatory pathways like Mitogen-Activated Protein Kinase (MAPK) and PI3K-AKT that co-operate in EGFR and Yki driven cancer.

Interestingly, many of our identified candidates from the screen are already classified as oncogenes by the cosmic cancer gene census. We tried to identify these molecules that might have a dual role in tumorigenesis, functioning both as an oncogene and as a tumor suppressor depending on the upstream cues/signaling context. One such molecule we selected for our study was corkscrew (Csw) a non-receptor protein tyrosine phosphatase that was identified from the genome-wide RNAi screen to function as a negative growth regulator exclusively in Yki driven cancer. We examined the tumor suppressor role (if any) of Csw ortholog, Tyrosine-protein phosphatase non-receptor type 11 (*PTPN11*), also known as, Src homology phosphatase (SHP2) from literature mining, clinical metadata analysis, and validated our hypothesis using cell culture techniques.

Csw and its ortholog, *PTPN11*/SHP2 consists of two N-terminal SH2 domain (N-SH2 and C-SH2), a classic phosphatase domain split by cysteine and serine-rich inserts, a C terminal tail with Y-542 required for its activation, and a proline-rich motif in the C terminal end to bind to SH3 domain-containing protein (Neel, Gu, and Pao 2003) (Figure 1.2). Csw has two human orthologs, *PTPN6* and *PTPN11* (https://www.flyrnai.org/cgi-bin/DRSC_orthologs.pl). *PTPN11*/SHP2 primarily helps in sustained growth factor signaling and promotes cellular proliferation and migration (Neel, Gu, and Pao 2003) (Figure 1.3).

Figure 1.2: (A) shows *PTPN11/SHP2* in open conformation with N terminal N-SH2 and C-SH2 domains, a classic phosphatase domain, and a c terminal tail with tyrosine residues. (B) shows activation of the closed-loop conformation of *PTPN11/SHP2* by binding protein (BP) or auto-activation by phosphorylated tyrosine in C terminal tail. Image reproduced from Neel, Gu, and Pao 2003.

Figure 1.3: Schematic showing *PTPN11/SHP2* participates in downstream signaling of receptor tyrosine kinases (RTKs) and cytokine receptors and activates the MAPK pathway to control

proliferation, growth, and migration. Image adapted from (Aceto et al. 2012; Neel, Gu, and Pao 2003).

PTPN11/SHP2 is the first identified phosphatase to have an oncogenic function and plays a crucial role in positive feedback signaling of the EGFR pathway (Aceto et al. 2012). The dual-specificity of a molecule in tumorigenesis is not a new concept in the field of cancer research. Previous studies have reported molecules to have a dual role in tumorigenesis. The two variants of the P53 molecule, TP53 variant with the transactivation domain functions as a tumor suppressor and activate cell cycle arrest genes, apoptosis, and maintains genomic stability while the Δ NP53 (without the N terminal transactivation domain) variant has oncogenic functions and helps in cellular survival and self-renewal of stem/progenitor cells (Candi et al. 2014). Similar to P53, its paralogs P63 and P73 also show dual behaviour where Δ NP63 and Δ NP73 variant overexpression induces tumorigenicity in the liver and skin respectively (Costanzo et al. 2014a). In addition to P53, YAP1, a known oncogene in solid tumors is also reported to have a tumor suppressor role. Nuclear YAP1 binds and stabilizes TP73 and induce apoptosis by the Ras association domain family 1 isoform A (RASSF1A) (Strano and Blandino 2007). YAP1 is also known to be phosphorylated by cellular homolog of Abelson murine Leukaemia (ABL) Kinase (c-Abl) at tyrosine 357 upon DNA damage and stabilize P73 thereby preventing its degradation by ITCH (a ubiquitin ligase) (Keshet et al. 2014). *PTPN11*/SHP2, the molecule of our interest in this study, is also reported to function as an oncogene potentially by activation of Ras/MAPK pathway in breast cancer (Patel et al. 2016), colorectal cancer (Prahallad et al. 2015), lung cancer (Schneeberger et al. 2015), glioblastoma (Feng et al. 2012), prostate cancer (K. Zhang et al. 2016), and hematologic malignancies (Richine et al. 2016). Contrarily, *PTPN11*/SHP2 has also been reported to have a tissue-specific role and to function as a tumor suppressor in Hepatocellular Carcinoma (HCC) and Esophageal Squamous Cell Carcinoma (ESCC) (Bard-Chapeau et al. 2011; Qi et al. 2017). *PTPN11*/SHP2 is also reported to mediate Retinoblastoma(Rb)/ Elongation factor 2 (E2F) associated apoptotic response (Morales et al. 2014)

In our study, we tried to investigate the dual role of *PTPN11*/SHP2 in a specified tissue and examined the context of its dual role, if any, in solid tumors, with a major focus on breast epithelial cancer. Breast cancer affects nearly 2.1 million women each year and accounts for nearly 15% of deaths among women (WHO,2020, <http://www.who.int>). Breast cancer is highly heterogeneous and is clinically classified as Hormone receptor-positive, Human Epidermal growth factor

Receptor 2 (HER2) positive, and Triple Negative Breast Cancer (TNBC) each with a specific outcome and therapeutic targets (Perou et al. 2000). We looked into breast cancer clinical cohorts availed by The Cancer Genome Atlas (TCGA) and the Molecular Taxonomy of Breast Cancer International Consortium (METABRIC) and also looked into solid tumors like lung adenocarcinoma, ovarian cancer, prostate cancer, and colorectal cancer availed by TCGA. Phosphoprotein data for *PTPN11/SHP2* was availed only for breast cancer by TCGA. Hence, we limited our study to breast cancer, validated our retrospective analysis across to datasets, and correlated clinical parameters to copy number status in METABRIC data and both copy number status and phosphoprotein expression of *PTPN11/SHP2* in TCGA to identify *PTPN11/SHP2*'s role in breast tumorigenesis. Furthermore, *PTPN11/SHP2* ortholog was reported to function as a tumor suppressor in the Yki screen but not in the EGFR screen in our laboratory. This is intuitive as *PTPN11/SHP2* is a positive regulator of EGFR signaling. This was indeed interesting as the tumor suppressor role of *PTPN11/SHP2* in YAP1 driven breast cancer is still nascent and was investigated in our study.

Chapter 2: Biological Interactome Study

2.1: Introduction

Tumorigenesis is a multistep process that enables cells to gain a proliferative advantage, avert death or immune response, evolve, and invade into the adjacent organs, a process referred to as metastasis (Hanahan and Weinberg 2011). With the advent of data science, large scale genomics/transcriptomics/proteomics data from several patients or cancer cells could be compared and subjected to multifactorial analyses. The advantage of developing such interactome is, one could identify multiple causative factors, all of which together orchestrate tumorigenesis. Genetic approaches and sequencing efforts on genome landscapes have identified major driver mutations affecting one or more signaling pathways driving cancer (Vogelstein et al. 2013). Insights into these signaling networks have further progressed our understanding of previously unidentified “silent players” in cancer which neither shows high mutational frequency nor shows differential expression profiles; however plays an essential role in the biological interactome affecting major cancer-related pathways (Ruffalo, Koyutürk, and Sharan 2015).

Protein-Protein interaction network (PPIN) studies in yeast have largely helped in the understanding of structural and functional modules of genes and reflect their essentiality (Kim et al. 2012; Lu et al. 2010). Although highly controversial, the role of hub genes in large interactome has shown to follow the centrality lethality rule wherein a higher degree of interaction tends to make these genes essential for the organism and lethal if these are deleted (Jeong et al. 2001; Khuri and Wuchty 2015). Hubs genes identified in yeast mostly tend to either exist as structural complexes or participate in overlapping functional processes (He and Zhang 2006; Lu et al. 2010; Ning et al. 2010). Non-clustered-non-co expressed genes in hubs form connecting and organizing modules and deletion mutation of these genes are not lethal, unlike the clustered-co-expressed hub genes that are necessary to form protein complexes important for biological processes (Pang, Sheng, and Ma 2010).

A genome-wide RNAi mediated screen using a wing imaginal disc of *Drosophila* as a model was conducted in our laboratory to study epithelial tumorigenesis. This study identified hundreds of negative regulators whose suppression co-operates to enhance Yki driven neoplasia and less than a hundred negative regulators to be involved in EGFR driven neoplasia. We also report from an independent screen, potential candidate genes that suppress EGFR driven neoplasia. The larger number of positives identified in the Yki screen could reflect a higher sensitivity of Yki and its interacting partners or low specificity of the screen resulting in a larger number of false positives (Groth et al. 2019; Vissers et al. 2016). Understanding these negative and positive regulators in a functional network module would allow us a detailed understanding of the pathways involved in EGFR and Yki driven neoplasia. The screen identified a vast repertoire of potential context-specific negative growth regulators that co-operate exclusively with Yki or EGFR in cancer progression. This screen identified previously known targets and a myriad of new context-specific tumor suppressors that could have potential prognostic value in human cancer research. This study involves identifying the essential genes responsible for Yki and EGFR driven neoplasia and identify their closest human orthologs that play a significant role in major growth regulatory pathways. These orthologs could have diverged considerably in sequence homology however functionally possibly remain part of similar protein complexes and participate in similar pathways. Such evolutionary conserved pathways are important and need to be identified to help our understanding of cancer which is highly evolving and heterogeneous.

2.2: Experimental approach

2.2:1: Identification of human orthologs of RNAi mediated *Drosophila* screen

Vienna *Drosophila* Resource Center (VDRC), <https://stockcenter.vdrc.at/control/main>, which provides the KK RNAi used for the RNAi screen of *Drosophila* genome in our laboratory, is predicted to have many non-specific targets. VDRC site provides information on whether an RNAi used had any non-specific target or only a specific target. To rule out any spurious results, we sorted only KK RNAi with one specific target for all our analyses of human orthologs. Prediction of human orthologs of selected candidates was performed using the *Drosophila* RNAi Screening Center (DRSC) integrative ortholog prediction tool (DIOPT). DIOPT is a human ortholog prediction tool. Orthology predictions were based on the integration of all twelve

prediction tools including phylogeny-based orthology prediction tools, orthology prediction from genome-wide sequence-based prediction tools, and protein-protein interaction network-based prediction tool and each tool assigning a score of 1 to *Drosophila* orthologs in humans; A scale of 2-11 score was used for selecting all orthologs of the candidate genes in our analysis.

2.2.2: Network Analysis

Search Tool for the Retrieval of Interacting Genes/Proteins (STRING 10) is a PPIN database that integrates knowledge obtained from other PPIN databases such as Molecular INTERaction (MINT), Human Protein Reference Database (HPRD), Biological General Repository for Interaction Database (BioGRID), Database of Interacting proteins (DIP) and Reactome, etc (<https://string-db.org/>). STRING 10, the most updated version since 2000, allows prediction of protein-protein interactions in a query organism by transferring the interaction observed in one organism to the query organism; STRING 10 build a network from information available not only in primary databases to which it is integrated but also from curated databases with experimental evidence for a protein pair interaction and from text mining evidence from full-text articles using an algorithm that uses part of speech tagging, chunking grammar, and co-occurrence of name of protein pairs within paragraphs and sentences (von Mering et al. 2003, 2005). STRING 10 also uses the information of co-occurrence, co-expression, gene neighbourhood, gene fusion, and does sequence similarity search to predict functional interaction between proteins (Szklarczyk et al. 2015). Each predicted interaction is benchmarked to the Kyoto Encyclopedia of Genes and Genomes (KEGG) database; interacting proteins in the same KEGG map are accounted as positives, if not, they are accounted as false positives (von Mering et al. 2003). Each protein in the network appears as a node and interaction between proteins forms the edges of the network (Szklarczyk et al. 2017). All string 10 maps were built with a high confidence strength (0.7) supported by evidence from co-expression, experimental evidence, and evidence from co-occurrence, gene neighbourhood, gene fusion, curated database, pre-computed orthology predictions and text mining evidence, and Markov Clustering (MCL) clustering coefficient of 0.2 was used for robust clustering of the interactome (Brohée and van Helden 2006).

2.2.3: Pathway enrichment analysis:

STRING 10 allows the user to understand statistically enriched biological functions in a network. We used String 10 to identify the Gene Ontology (GO) molecular processes and KEGG pathways

enriched for the positives on the screen. Significantly enriched groups were given as <0.05 false discovery rate (FDR) values.

2.3: Results

2.3.1: Identification of Human orthologs

Previous work in our laboratory screened 9032 and 9137 RNAi lines to identify negative growth regulators whose suppression co-operates in Yki and EGFR driven neoplasia. 9335 RNAi lines were screened independently in our laboratory to identify positive regulators of growth co-operating in UAS-EGFR+ SOCS36E RNAi tumors. The summary of the identified candidates is provided in Table 1. Details of the list of the candidates are available in the Appendix (Table 2.3.1). We identified 1514 and 129 human orthologs of the 904 and 73 confirmed positives in Yki and EGFR screen respectively from our analysis using DIOPT. We predicted many of these candidates to play a putative tumor suppressor role in the context of YAP1 and EGFR driven human epithelial cancer. We observed less than 1% overlap in the identified tumor suppressor between Yki and EGFR screen candidates with most of the identified positives being context-specific and co-operating specifically in YAP1 or EGFR driven neoplasia. In the SOCs screen, we identified 66 putative genes that co-operate to promote EGFR driven neoplasia.

| | UAS-Yki | UAS-EGFR | UAS-EGFR+ SOCS36E RNAi |
|---|----------------|-----------------|-----------------------------------|
| Confirmed Positives | 904 | 73 | 32 |
| Confirmed positives with human orthologs | 611 | 46 | 31 |
| No of Human orthologs | 1514 | 129 | 66 |
| Overlap | 20 | | |
| Overlap with orthologs | 11 | | |

Table 1: Summary of analysis of genome-wide RNAi mediated screen of *Drosophila* genome to identify positive and negative regulators of growth co-operating with EGFR and Yki. The screen

was conducted in the wing imaginal disc of *Drosophila* larvae (Larval stage 3/L3), as an epithelial model system to study co-operativity in tumorigenesis and identification of context-specific putative tumor suppressors. The table is adapted from Groth et al., 2019.

2.3:2: String interactome of growth regulators identified in flies

We analysed a stringv10 map of identified positives in flies as shown in figure 2.3.2. We observed 904 positives in the Yki screen and were part of biological interactome with Protein-Protein Interaction (PPI) enrichment of $1.14E-06$. KEGG enrichment analysis to identify the pathways involved in Yki driven neoplasia for all 904 positives did not enrich for any significant biological pathway (Figure 2.3.2.A). However, KEGG analysis of only the 228 positives that constituted the large hub among other Yki positives with PPI enrichment of $<1.0E-16$ showed enrichment of hippo signaling, autophagy, apoptosis, metabolism, and ubiquitin (Ub) mediated proteolysis as major pathways that could be co-operating in Yki driven neoplasia (Figure 2.3.2.B). Details of GO and KEGG enrichment pathways of Yki positives are provided in Appendix Table 2.3.2.1 and Table 2.3.2.4. Analysis of the string v10 map of 73 positives of the EGFR screen does not show any major large hub but small clusters of genes with PPI enrichment of 0.000482. The positives identified in the EGFR screen were enriched in hippo signaling and autophagy processes (Figure 2.3.2.C). Details of GO and KEGG enrichment pathways of EGFR positives are provided in Appendix Table 2.3.2.2 and Table 2.3.2.5. Hippo pathway and autophagy were overlapping pathways that we report to co-operate with both EGFR and Yki driven neoplasia. Moreover, the 32 positives identified in the UAS-EGFR+SOCS RNAi screen show small clusters with PPI enrichment of 0.0122, and KEGG analysis show enrichment of pathways involved in RNA and protein turnover and mammalian target of rapamycin (mTOR) signaling (Figure 2.3.2D). One of the candidate genes *csw*, positive only in the Yki screen was located in the center of the hub, Figure 2.3.2.B, the relevance of which we would be discussing in the later chapters. Details of GO and KEGG enrichment pathways of SOCs positives are provided in Appendix Table 2.3.2.3 and Table 2.3.2.6.

(A)

(B)

(C)

(D)

Figure 2.3.2: (A) shows the analysis of the stringv10 map of all 904 positives of the Yki screen. (B) 228 of the 904 positives in the Yki screen formed a single large hub enriched in KEGG pathways including hippo signaling (red nodes) and autophagy (blue nodes). (C) Analysis of 73 positives of the EGFR screen forms many small clusters and are enriched in KEGG pathways like

hippo signaling (red nodes) and autophagy (blue nodes). (D) Stringv10 analysis of all 32 positives identified in the UAS-EGFR+SOCS RNAi screen also shows small clusters and no major large hub, details of pathway analysis reported in the appendix table.

2.3:3: String interactome of human orthologs of the growth regulators identified in flies

Stringv10 analysis of corresponding human orthologs identified using DIOPT of all candidate *Drosophila* genes from the three independent screens is shown in figure 2.3.3.1514 human orthologs of the candidates identified in the Yki screen formed a large biological interactome with PPI enrichment of $1.0E-16$. KEGG enrichment analysis identified the pathways involved in YAP1 driven neoplasia for all 1514 positives which included MAPK signaling, autophagy, Hippo signaling, metabolic pathways, and PI3K-AKT among many others (Figure 2.3.3A). However, KEGG analysis of only the 731 hub genes among other YAP1 positives with PPI enrichment of $<1.0E-16$ showed enrichment of MAPK signaling, autophagy, Hippo signaling, metabolic pathways, PI3K-AKT, and genes of the cell cycle to co-operate in YAP1 driven neoplasia (Figure 2.3.3B). Details of GO and KEGG enrichment pathways of YAP1 positives are provided in Appendix Table 2.3.3.1, Table 2.3.3.2, Table 2.3.3.5, Table 2.3.3.6. String v10 analysis of 129 positives of the EGFR screen did not show us any major large hubs but two small hubs of genes with PPI enrichment of $<1.0E-16$. The human orthologs of positives identified in the EGFR screen were also enriched for hippo signaling, MAPK signaling, and metabolism among other major pathways (Figure 2.3.3). Details of GO and KEGG enrichment pathways of EGFR positives are provided in Appendix Table 2.3.3.3 and Table 2.3.3.7. We report from our string analysis and GO/KEGG enrichment study, Hippo pathway and MAPK pathway are the major overlapping pathways that co-operate with both EGFR and YAP1 driven neoplasia in humans. 66 positives we identified in the UAS-EGFR+SOCS RNAi screen showed one large hub and several small clusters with PPI enrichment of $<1.0E-16$. KEGG analysis of these 66 confirmed orthologs shows enrichment of pathways involved in RNA and protein turnover and mTOR signaling (Figure 2.1D). Csw ortholog *PTPN11/SHP2* like in the fly hub was located in the center of the human biological hub, interacted with cell cycle-related genes, and the MAPK signaling components, the relevance of which will discuss in later chapters. Details of GO and KEGG enrichment pathways of the UAS-EGFR+SOCS RNAi screen are provided in Appendix Table 2.3.3.4 and Table 2.3.3.8.

(A)

(B)

(C)

(D)

Figure 2.3.3: Stringv10 analysis of all 1514 human orthologs of positives of Yki screen. KEGG analysis shows enrichment of metabolic pathways, genes involved in proteoglycans in cancer (not shown in the figure). Details of all pathways are available in Appendix Table 2.3.3.1, Table 2.3.3.2, Table 2.3.3.5, Table 2.3.3.6. (A) shows 731 of 1514 genes were observed to form a single large hub and enriched in KEGG pathways like Hippo signaling, mTOR signaling, several metabolic pathways, PI3k-AKT, MAPK, Ras signaling pathways. (B) shows the hub separately.

(C) shows 129 human orthologs of positives of the EGFR screen were observed to form two small hubs and were also enriched in KEGG pathways like hippo signaling, MAPK, and Hedgehog signaling and autophagy. (D) shows Stringv10 map of all 66 positives identified in the UAS-EGFR+SOCS RNAi screen shows small clusters and one major large hub enriched in JAK-STAT, ERbB signaling pathways among others.

2.4: Discussion

The screen identified 904 and 73 candidate genes to co-operate with Yki and EGFR driven tumorigenesis respectively. Our analysis suggested 570 candidates out of 904 positives identified in the Yki screen had one or more human orthologs mapping to a total of 611 human genes. 46 of the 73 EGFR positives could be mapped to 50 human genes. While 32 of the SOCs positive candidates could be mapped to 31 human genes.

We report the positives identified in the Yki screen formed a distinct large hub from our network analysis using Stringv10 as observed among the fly genes and their corresponding human orthologs. We do not have similar findings among positives identified in EGFR driven neoplasia. We also found many of the hub genes in the Yki screen were conserved in the hub of the human growth network. These included p53, Shaggy (*sgg*), PRKC group of genes, *csw*, MAPKs, wnts, and many protein turnovers related genes. Interestingly, we also identified many lipid metabolic genes to be conserved in the biological hub in Yki driven cancer. Most of these evolutionarily conserved genes were also among the largest interactors in the hub. Human orthologs among these essential genes based on the largest number of interactors in Yki driven tumorigenesis had 71 or fewer interactors.

The large interactome co-operating in Yki driven cancer in our analysis suggests, hippo signaling functions as a single most contributing factor controlling many growth-related pathways such as cell cycle, DNA damage, metabolism, death, and proliferation. Our observation confirms the previously reported role of Yki/YAP in biological processes including proliferation, death, metabolism, and DNA damage (Moroishi, Hansen, and Guan 2015). Hippo pathway has been previously reported to interact with EGFR (Herranz et al. 2012), we also report a similar finding and identify the hippo pathway to be sufficient to drive EGFR driven tumors. Furthermore, our findings suggest, the fat/hippo pathway and autophagy process play a relevant role in both Yki and EGFR driven cancers and these pathways are highly conserved in humans. We identify

exclusively, protein turnover to be among other important processes that regulate growth in Yki driven tumorigenesis but not in EGFR driven tumorigenesis. We also report autophagy and hippo pathway to be conserved and important from Yki driven tumors. This study is in coherence with the already reported literature on the role of YAP1 in growth control via Ub related pathways and autophagy related pathways. YAP1 has been reported to control proliferation via autophagy (Pavel et al. 2018), and while Ub protein, ITCH is reported to promote I κ B degradation and YAP1 activity (Salah and Aqeilan 2011). In summary, a larger interactome observed in Yki driven cancer and with the hippo pathway being a major contributor of EGFR driven tumorigenesis puts the Hippo pathway as a rate-limiting biological pathway that modulates the balance between homeostatic growth and cancer.

Although, Yki and EGFR further seem to merge and employ in the course of evolution similar signaling pathways including MAPK, estrogen, wnt, hedgehog signaling pathways, proteoglycans in cancer to control biological processes like cell cycle and cell death in initiating tumorigenesis. Contrarily, estrogen signaling, MAPK signaling, autophagy, proteoglycans in cancer seems to function as a double-edged sword. These pathways seem to function in a context-specific manner and might be cue driven as we observe suppression of candidates of these pathways co-operate with EGFR driven neoplasia and alternatively helps in the suppression of EGFR overexpressing and SOCs suppressed tumors.

Understanding the molecular cues in the perspective of cancer becomes more challenging with the vulnerability of dual roles of signaling pathways. One of the prominent candidates from the Yki screen, Csw, a non-receptor protein tyrosine phosphatase was interesting in the perspective of molecular duality and role in tumorigenesis. Csw human ortholog *PTPN11/SHP2* was a prominent oncogene in solid tumors and hematologic malignancies (Sondka et al. 2018). In the human interactome map, *PTPN11/SHP2* appears to be part of the main hub connecting multiple pathways. Interestingly, it was negative in EGFR and EGFR+SOCs RNAi screen but positive in the Yki screen. Although *PTPN11/SHP2* participates in positive feedback signaling of the EGFR pathway (Patel et al. 2016), it might not be essential to this pathway. Indeed, its suppression does not rescue EGFR+SOCs RNAi driven tumors. This puts forth the question of whether *PTPN11/SHP2* is a context-specific molecule and would be interesting to speculate its tumor suppressor role in YAP1 driven epithelial cancers, which is studied in more detail and reported in the subsequent chapters.

Chapter 3: Clinical Relevance of Csw ortholog *PTPN11/SHP2* in Breast cancer

3.1: Introduction

Breast cancer is the most heterogeneous among solid tumors (Polyak 2011). Molecularly it is categorized into hormone receptor-positive subtype (ER/PR), i.e. Estrogen receptor (ER) and Progesterone receptor (PR) positive, Human Epidermal growth factor Receptor 2 (HER2) driven subtype, and Triple Negative Breast Cancer (TNBC) subtype lacking the ER, PR, and HER2 oncogenic receptors, each of which has different expression pattern of genes (Perou et al. 2000). A minimum of 50 genes set from 1906 “intrinsic” genes analysed by hierarchical clustering further classify breast cancer into Luminal A (ER/PR+, Ki67 low), Luminal B (ER/PR+, Ki67 high), HER2+, and Basal subgroup, referred to as the Predictive analysis of microarray (PAM 50) subset and is often used to evaluate the risk of disease and prognosis (Bernard et al. 2009).

With the advent of molecular techniques, a combined analysis of copy number changes and gene expression patterns of 2000 primary breast tumor specimens with long term follow up of patients (the METABRIC dataset) further helped identify novel subgroups (Curtis et al. 2012). Furthermore, integration of several platforms ranging from whole-genome sequencing, miRNAs sequencing, RNA sequencing, copy number arrays, and reverse-phase protein arrays (RPPA) in the TCGA dataset has helped in better understanding of the molecular complexity of breast cancer in the recent past (Ciriello et al. 2015). Whole-genome sequencing of 560 breast cancer patients identified driver mutational signatures and categorized 93 mutated cancer genes (Nik-Zainal et al. 2016). Quantification of phosphoprotein and protein expressions of 171 cancer genes across 403 breast tumor samples stratified breast cancer into seven subgroups of which overexpression of EGFR and HER2 correlates well with their corresponding phosphorylated tyrosine residues in these RPPA defined HER2 enriched subgroup (Ciriello et al. 2015). This study aimed to identify additional therapeutically important subsets of breast cancer. We performed a retrospective analysis of clinical metadata to find how driver genes like *csw* ortholog *PTPN11/SHP2* associate with the prognostic status of breast cancer patients and whether *PTPN11/SHP2* plays a dual role in the genesis of the disease.

PTPN11/SHP2 the human ortholog of Csw is a bonafide oncogene as categorized by the cosmic cancer gene census (Sondka et al. 2018). *PTPN11/SHP2* knockdown reduces the invasiveness of HER2 overexpressing MCF10A cells while its expression allows activation of v-myc and zeb1 to induce invasive behaviour of HER2 overexpressing MCF10A cells (Aceto et al. 2012). *PTPN11/SHP2* has been reported to be an independent predictor of poor overall survival of Luminal A and Luminal B/HER2 subtypes as observed in 1401 breast cancer specimens, 46% of which showed a positive correlation of *PTPN11/SHP2* expression to the aggressive clinical parameters (Muenst et al. 2013). *PTPN11/SHP2* is also reported to promote BASAL like tumorigenesis possibly by regulating expression and signaling of RTKs like EGFR, Fibroblast Growth Factor Receptor (FGFR), and c-Met in the basal-like and triple-negative breast cancer (BTBC) cell line (Mataalkah et al. 2016). We also wanted to study the ambiguous role of *PTPN11/SHP2* in breast cancer subtypes, validate our findings of the Yki screen, and evaluate the negative growth regulatory role of Csw ortholog *PTPN11/SHP2* in breast cancer. We examined clinical metadata including METABRIC 2012 and TCGA 2015 and analysed the correlation of *PTPN11* copy number aberration and SHP2 phosphoprotein expression to clinical parameters to understand its clinical relevance and find its dual role, if any, in breast cancer.

3.2: Methods

For all analyses, data from METBRIC 2012 and TCGA 2015 was used. METABRIC data was downloaded from cbiportal (Cerami et al. 2012) and TCGA GRCh38 data from the Genomic Data Commons (GDC) data portal using the GDC R tool (Morgan M, Davis S (2019).

GenomicDataCommons:NIH/NCIGenomicDataCommonsAccess.

(<https://bioconductor.org/packages/GenomicDataCommons>,
<http://github.com/Bioconductor/GenomicDataCommons>).

The TCGA RPPA level 4 data was downloaded from FireBrowse (firebrowse.org). The clinical metadata analysis was performed using R (version 3.6.1, platform x86_64-w64-mingw32/x64). Packages used for analysis include survminer_0.4.6, ggpubr_0.2.3, magrittr_1.5, survival_2.44-1.1, forcats_0.4.0, stringr_1.4.0, purrr_0.3.3 8, readr_1.3.1, tidyr_1.0.0, tibble_2.1.3, ggplot2_3.2.1, tidyverse_1.2.1, dplyr_0.8.3. For TCGA RPPA data analysis additional packages Hmisc_4.2-0, Formula_1.2-3, lattice_0.20-38 were used. Kruskal-Wallis, Wilcoxon, and log-rank test were used for statistical analysis, $p < 0.05$ was considered significant.

3.3: Results

3.3.1A: Correlation of *PTPN11*/*SHP2* copy number changes and clinical parameters of METABRIC 2012 breast cancer patient cohort

3.3.1A.1: Correlation of *PTPN11*/*SHP2* copy number changes and clinical parameter of patients at diagnosis:

We examined the statistical association of *PTPN11*/*SHP2* copy number loss to clinical parameters in breast cancer to understand its oncogenic or tumor suppressor nature by loss of function genetics. All analyses include associations of *PTPN11*/*SHP2* GISTIC scores to clinical parameters like age, stage, lymph node status, the grade of the tumor, and tumor size availed from the METABRIC data set (Tables S3.3.1A.1). There was only one instance of homozygous deletion and 3 instances of homozygous duplication (GISTIC -2 and +2 respectively) which were therefore not analysed separately from the heterogeneous changes (GISTIC score of -1 and +1 respectively). There were a few cases with claudin low status without any PAM50 classification and hence were excluded from the analysis. We confirmed *PTPN11*/*SHP2* gene expression correlated well with its corresponding copy number changes in METABRIC patients (A). From our analysis, we observe *PTPN11*/*SHP2* copy number loss correlated to early onset of disease with a mean age of 59.1 ± 13.8 years (B), larger tumor size (28.2 ± 19.2 mm) (C), significantly increased grade 3 tumors (D), and increased late-stage cancer (E) at diagnosis and no changes in lymph node positivity (F) as compared to patients with wild type copy number or copy number gain of *PTPN11*/*SHP2*.

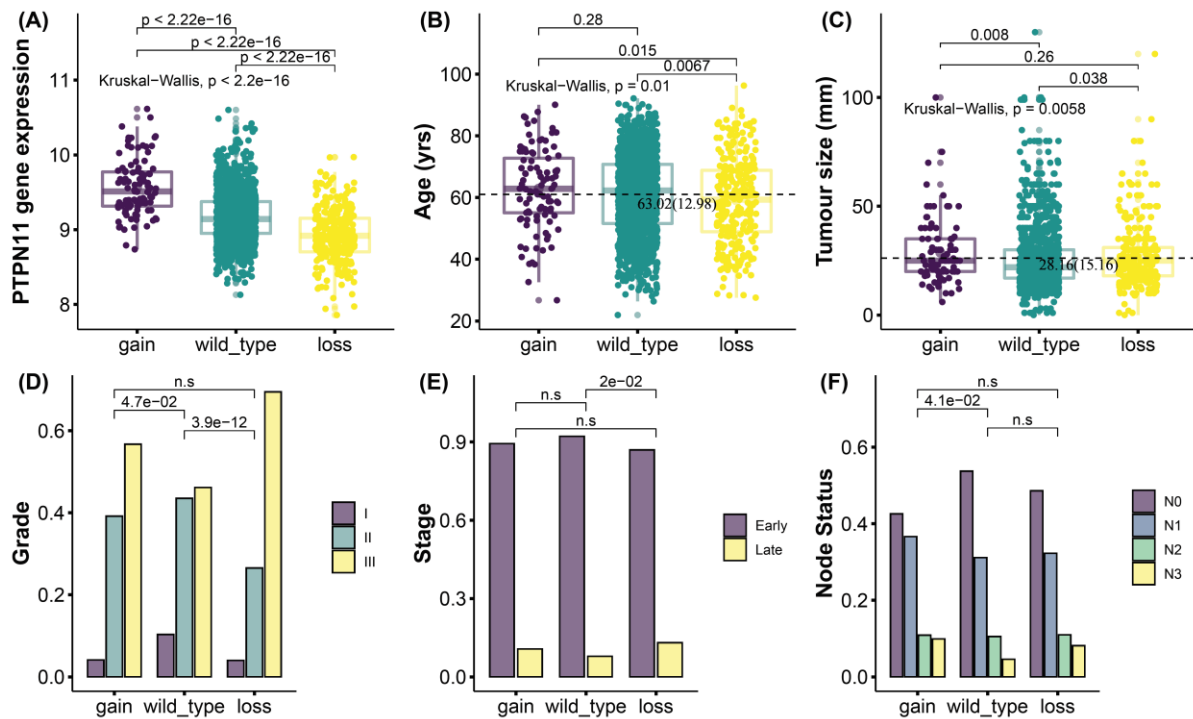

Figure 3.3.1A.1: (A) shows *PTPN11*/SHP2 copy number changes significantly correlate to the *PTPN11* gene expression pattern. (B) shows loss of *PTPN11*/SHP2 correlates with early onset of disease with a mean age of 59.1 ± 13.8 years as compared to patients with wild type (WT) copy number (61.3 ± 12.8) or copy number gain (62.9 ± 13) of *PTPN11*/SHP2. (C) shows patients with *PTPN11*/SHP2 copy number loss associates with a significantly larger tumor size of 28.2 ± 19.2 mm compared to patients with WT copy number (25.6 ± 14.6 mm) but not different from patients with copy number gain (28.7 ± 14.6 mm). (D) shows patients with loss of *PTPN11*/SHP2 has significantly increased grade 3 tumors than patients with WT copy of *PTPN11*/SHP2 and no difference in the grade of tumors of patients with copy number gain. (E) shows with *PTPN11*/SHP2 copy number loss associates with increased late-stage cancer at diagnosis as compared to patients with WT copy of *PTPN11*/SHP2. (F) shows patients with copy number gain of *PTPN11*/SHP2 have increased lymph node metastasis as compared to WT. Y-axis of D, E, F shows the fraction of patients.

3.3.1A.2: Clinical Correlation of *PTPN11*/*SHP2* copy number changes and molecular parameters at diagnosis:

We examined the correlation of *PTPN11*/*SHP2* copy changes to the molecular subtype of breast cancer patients and gene expression of reported oncogenes Estrogen receptor 1 (ESR1), HER2, and YAP1. Copy number loss of *PTPN11*/*SHP2* correlates to low ESR1 expression (A) and higher YAP1 expression (C) however there was no change in HER2 expression (B). Patients with copy number loss of *PTPN11*/*SHP2* negatively associates to ER status (E) and positively to HER2 status (D) and have a higher tendency to belong to TNBC (F) or the Basal subtype (G). We also see similar associations alternatively, as patients diagnosed with ER/PR subtype and Luminal A subtype negatively correlates to patients with copy number loss of *PTPN11*/*SHP2* (H, I). While patients in the TNBC subtype and Basal subtype shows a positive correlation to patients with copy number loss of *PTPN11*/*SHP2* (J, K). Details of the analysis are provided in Table 3.3.1A.2. Taken together, we observe copy number loss of *PTPN11*/*SHP2* associates to the most aggressive TNBC/Basal molecular subtype.

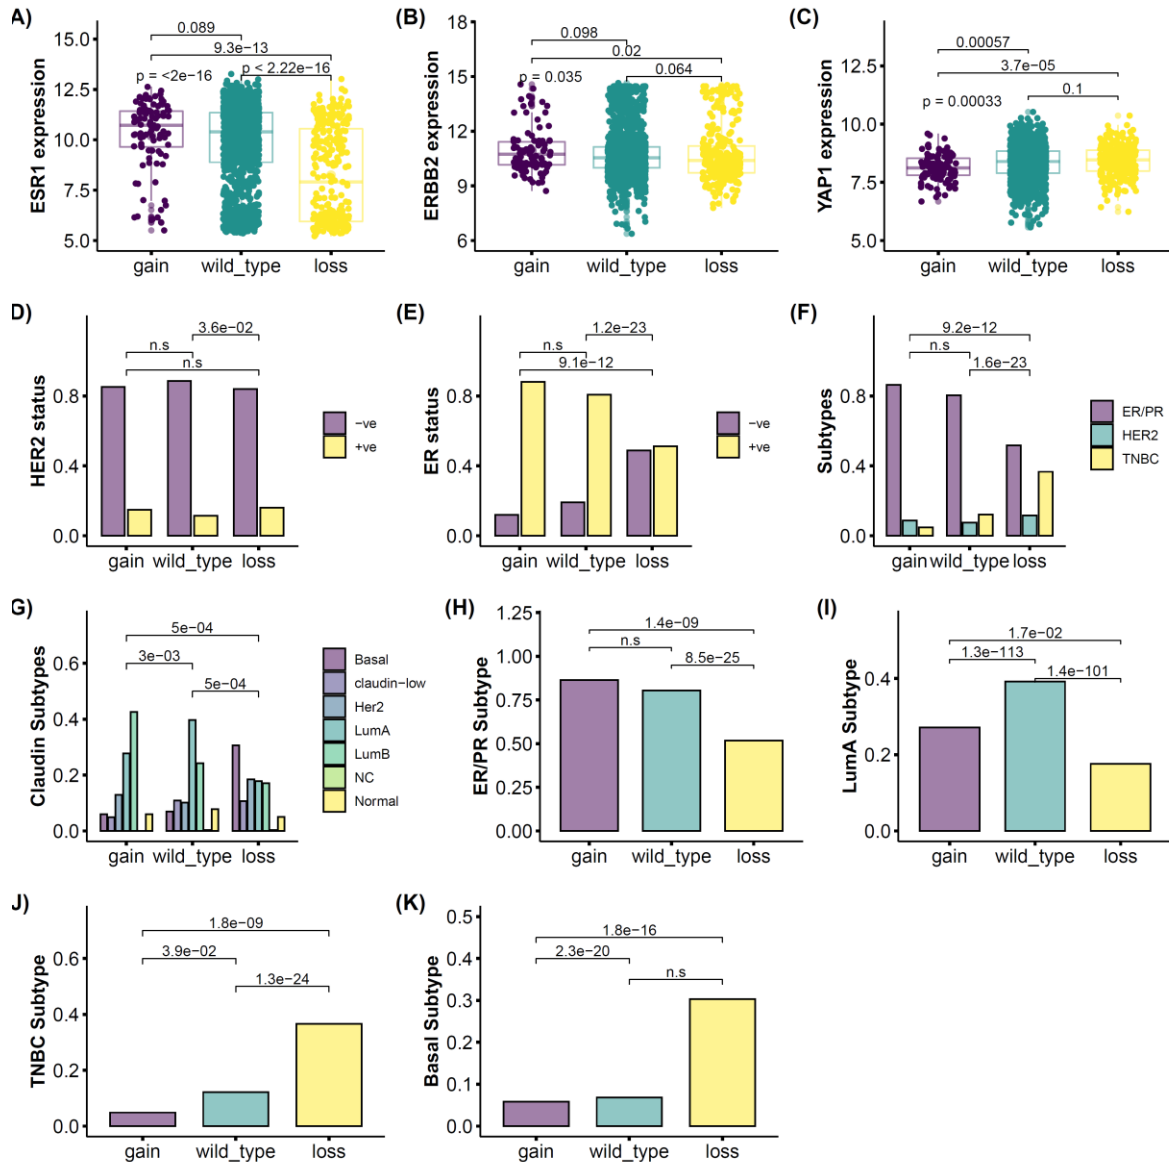

Figure 3.3.1A.2: (A) shows *PTPN11/SHP2* copy number loss associate with lower ESR1 expression (in comparison to gain and WT copy). (B) shows there is no association of *PTPN11* copy number changes to HER2 expression. (C) shows *PTPN11/SHP2* loss associates with higher YAP1 expression as compared to either gain of *PTPN11/SHP2*. (D) shows *PTPN11/SHP2* copy number loss associates with HER2 status and (E) shows *PTPN11/SHP2* copy number loss associates negatively associate with ER status. (F) and (G) shows *PTPN11/SHP2* copy number loss has strong associations with TNBC molecular subtype and claudin Basal subtype. The Y-axis shows the fraction subtype in each group. (H) shows *PTPN11/SHP2* copy number gain correlates to higher ER-positive breast cancer patients and (I) shows a correlation to Luminal (Lum) A

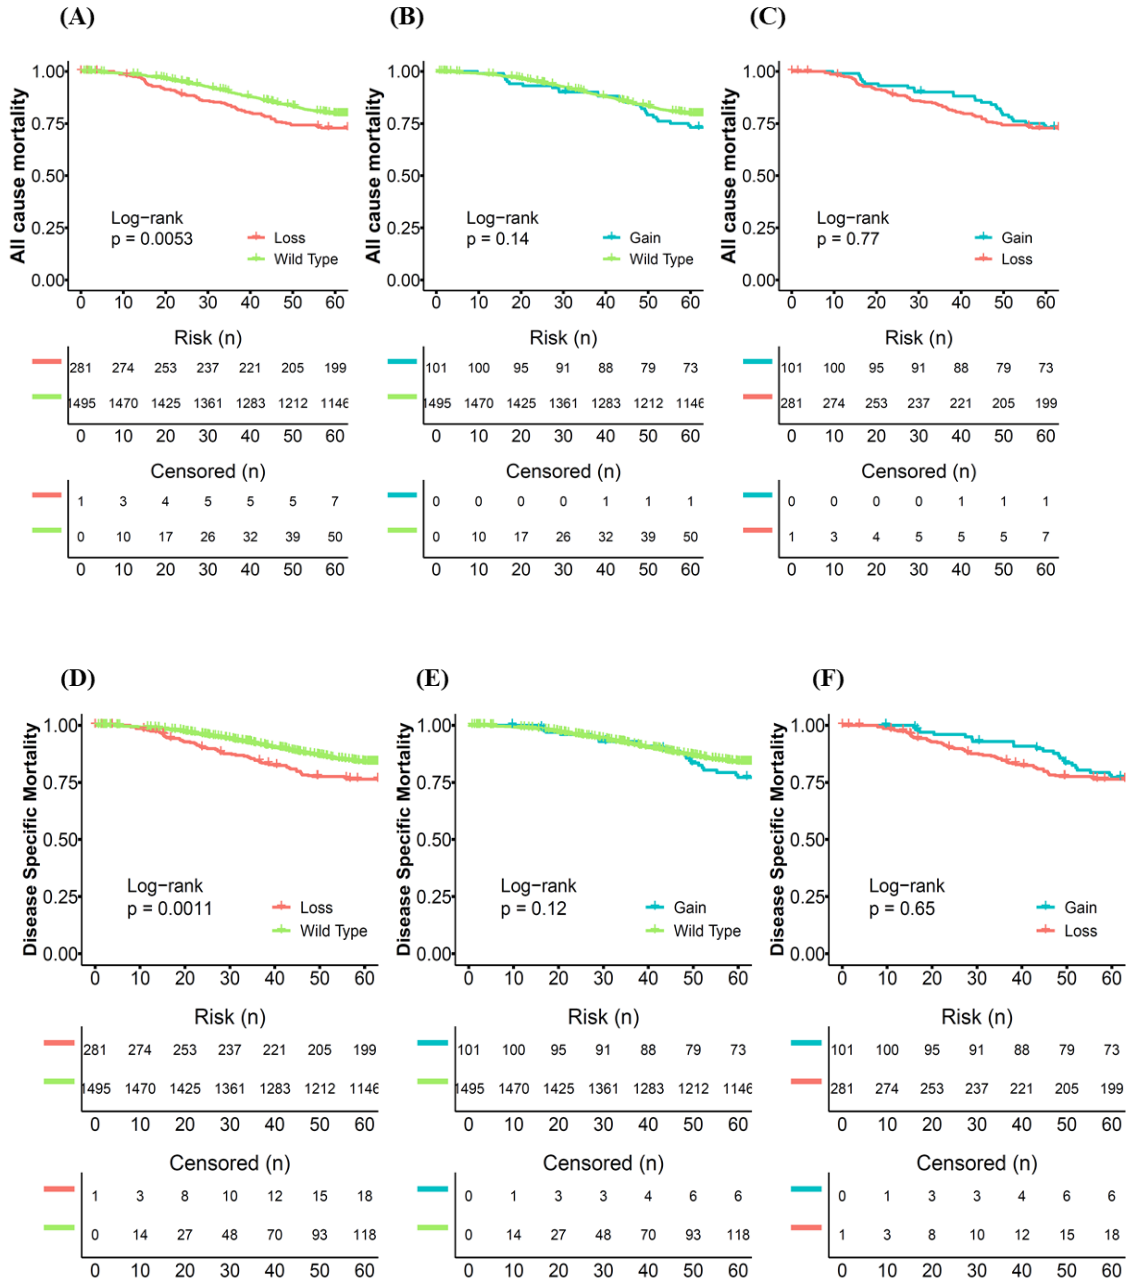

subtype as compared to patients with WT or loss of *PTPN11*/*SHP2*. (J) and (K) shows patients who are TNBC or Basal subtype positively associates with patients with *PTPN11*/*SHP2* copy number loss. The Y-axis of D-K shows the fraction of patients.

3.3.1A.3: Clinical Correlation of *PTPN11*/*SHP2* copy number change and survival outcome

We also investigated the influence of *PTPN11*/*SHP2* copy number changes on survival outcomes. We examined both overall survival (OS) and disease-specific survival (DSS) at 5 years and 4 years post-diagnosis to *PTPN11*/*SHP2* copy number changes. In overall survival, death due to any cause was taken as an event, while in disease-specific survival, only death due to disease was considered an event. The patients who survived post 5 years or 4 years were included in the study but censored at the respective endpoint.

We observed patients with *PTPN11*/*SHP2* copy number loss correlated to poor overall and disease-specific 5years survival as compared to wild type (A, D). There was no difference in survival, both OS and DSS of patients with *PTPN11*/*SHP2* wild type copy number and copy number gain (B, E) or in patients with copy number loss and copy number gain (C, F). We observe a similar trend even at 4 years, for patients with *PTPN11*/*SHP2* loss correlated to poor 4 years OS and DSS as compared to patients with wild type of the gene (G, J). There was no significant change in 4 years of survival both OS and DSS in patients with wild type copy numbers and patients with copy number gain (H, K). Interestingly, at 4 years endpoint, the patients with *PTPN11*/*SHP2* copy number loss had better DSS but not OS than patients with copy number gain of *PTPN11*/*SHP2* (I, L).

Five years of survival

Four years of survival

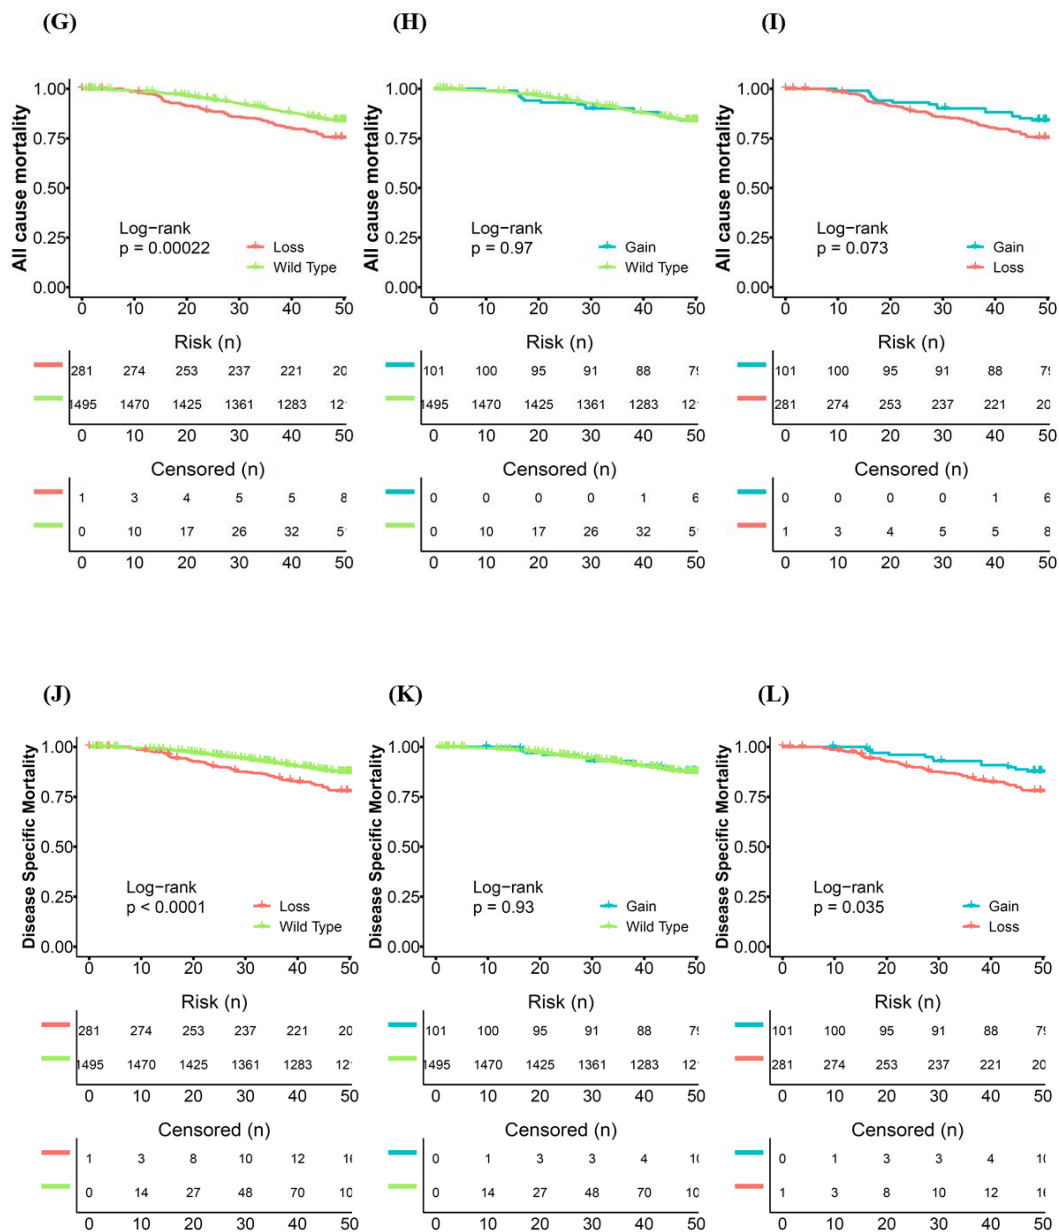

Figure 3.3.1A.3: (A) shows patients with *PTPN11/SHP2* copy number loss have 5 years of poor OS than patients with *PTPN11/SHP2* copy number gain. (B) shows there was no difference in 5 years OS of patients with either *PTPN11/SHP2* copy number gain or wild type copy number. (C)

shows there was no difference in 5 years OS of patients with *PTPN11*/*SHP2* copy number gain or patients with copy number loss. (D) shows 5 years DSS shows patients with *PTPN11*/*SHP2* wild type copy numbers have a better prognosis than patients with *PTPN11*/*SHP2* copy number loss. (E) shows there was no significant difference in 5 years DSS of patients with either copy number gain and wild type copy number. (F) shows no significant difference in DSS between patients with copy number loss and copy number gain. (G) and (J) shows at 4 years endpoint of survival, patients with *PTPN11*/*SHP2* copy number loss have a poor OS and DSS than patients with wild type copy number. (I) and (L) shows patients with *PTPN11*/*SHP2* copy number loss have poor OSS and DSS than patients with copy number gain at 4 years endpoint. (H) and (K) shows there was no difference in OS or DSS even at 4 years between patients with *PTPN11*/*SHP2* wild type copy number and copy number gain.

3.3.1B: Clinical Correlation of *PTPN11*/*SHP2* copy number changes in Luminal A Subtype:

From section 3.3.1A.2, we observed copy number gain of *PTPN11*/*SHP2* positively correlates to the claudin Luminal subtype. We examined the correlation of *PTPN11* copy number status with clinical parameters within the Luminal subtype to identify if *PTPN11*/*SHP2* has any specific (oncogenic or tumor suppressor) role. We also checked the association of *PTPN11*/*SHP2* to the disease-specific survival for 4 years in this subset. There was no significant association between *PTPN11*/*SHP2* copy number and age of patients at diagnosis (A), or their tumor size (B) and grade (C) in the luminal A subtype of patients. However, we report patients diagnosed with *PTPN11*/*SHP2* copy number loss correlated to late-stage cancer (D), more nodal positivity, and poor DSS. Details of the analysis are provided in table 3.3.1B. To summarise, *PTPN11*/*SHP2* copy number loss associates with the aggressive stage of Luminal A cancer with poor 4 years DSS in patients.

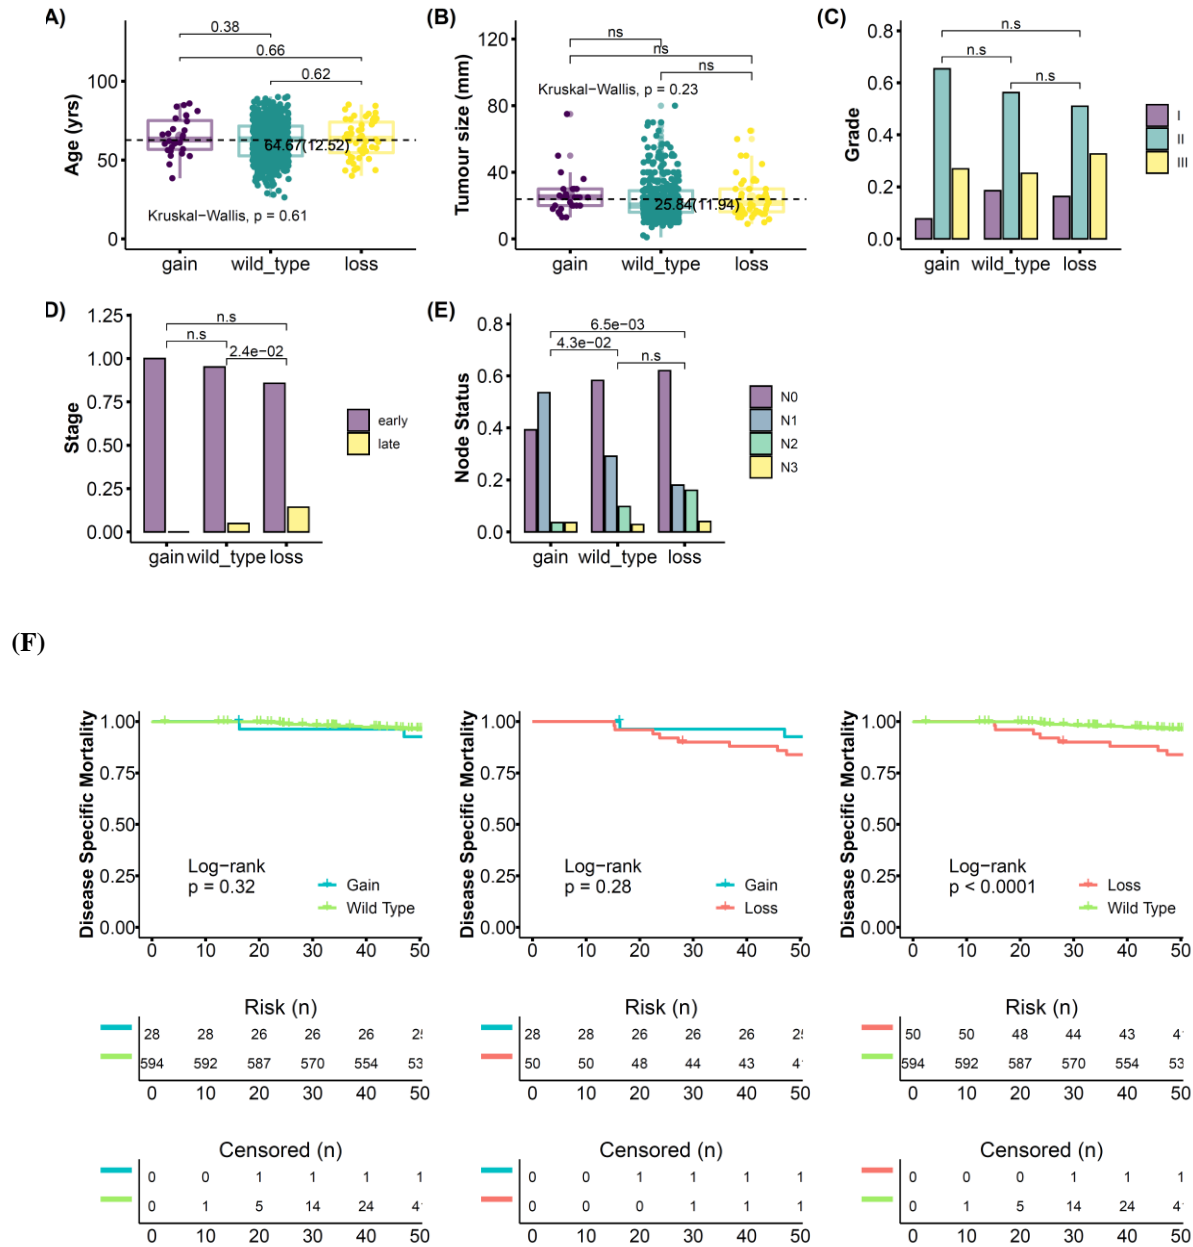

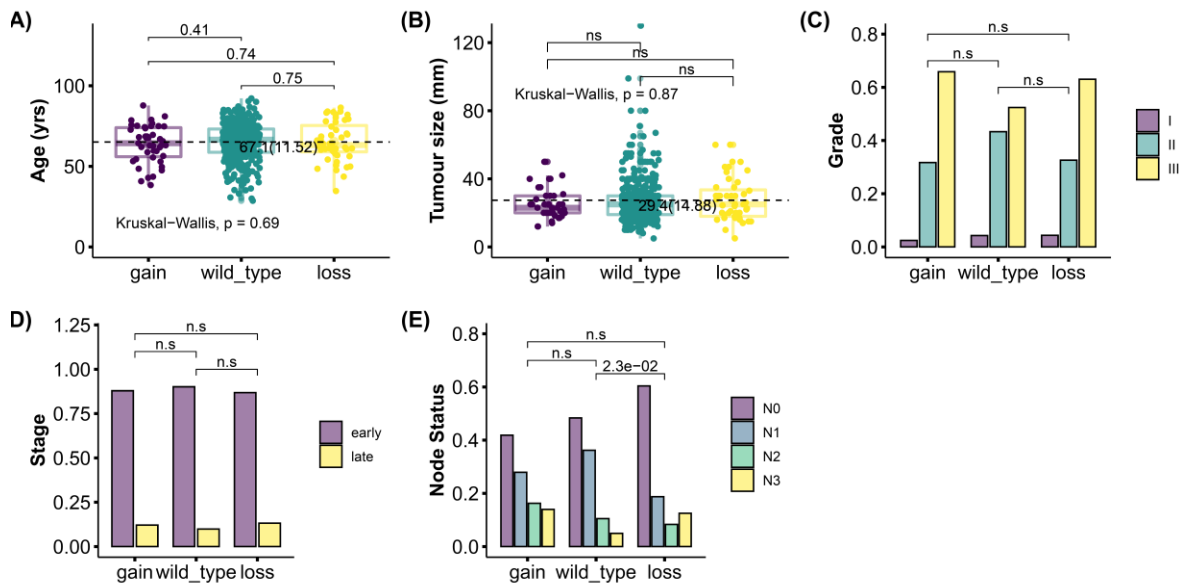

Figure 3.3.1B: In the Luminal A subtype, *PTPN11/SHP2* copy number changes do not correlate to (A) age, (B) tumor size, and (C) grade of patients at diagnosis. (D) shows copy number loss of *PTPN11/SHP2* associates with late-stage cancer at diagnosis as compared to patients with wild type copy number while there was no difference in stage of cancer between patients with copy number gain to patients with wild type copy number or copy number loss. (E) shows patients with copy number gain of *PTPN11/SHP2* also associates with more LN1 positivity and less LN2 than patients with copy number loss or patients with wild type copy numbers of *PTPN11/SHP2*; Patients with the wild type copy number of *PTPN11/SHP2* had more LN0 but also more LN2 than

patients with copy number gain of *PTPN11*/SHP2 at diagnosis. (F) shows loss of *PTPN11*/SHP2 further associated with poorer DSS as compared to wild type while there is no significant association to survival between patients with copy number gain and copy number loss or wild type copy number. Y-axis of C, D, E shows the fraction of patients.

3.3.1C: Clinical Correlation of *PTPN11*/SHP2 copy number changes in Luminal B subtype:

PTPN11/SHP2 copy number changes were also correlated to clinical parameters in the Luminal B+ subtype to study the association of (oncogenic and tumor suppressor) role of *PTPN11*/SHP2 in the luminal B subtype. The Luminal B group is characterized by HER2±, ER/PR+, and ki67 high. We do not observe a significant correlation between *PTPN11*/SHP2 copy number changes to any clinical parameters including age (A), tumor size (B), grade (C), stage (D) except Nodal positivity in the luminal B subtype of METABRIC cohort. Patients with copy number loss of *PTPN11*/SHP2 correlates to less lymph node positivity than patients with wild type copy number (E). We also do not observe a significant correlation of *PTPN11*/SHP2 copy number variations to the prognosis of the luminal B subtype of patients (F). Details of the analysis are provided in table 3.3.1C.

(F)

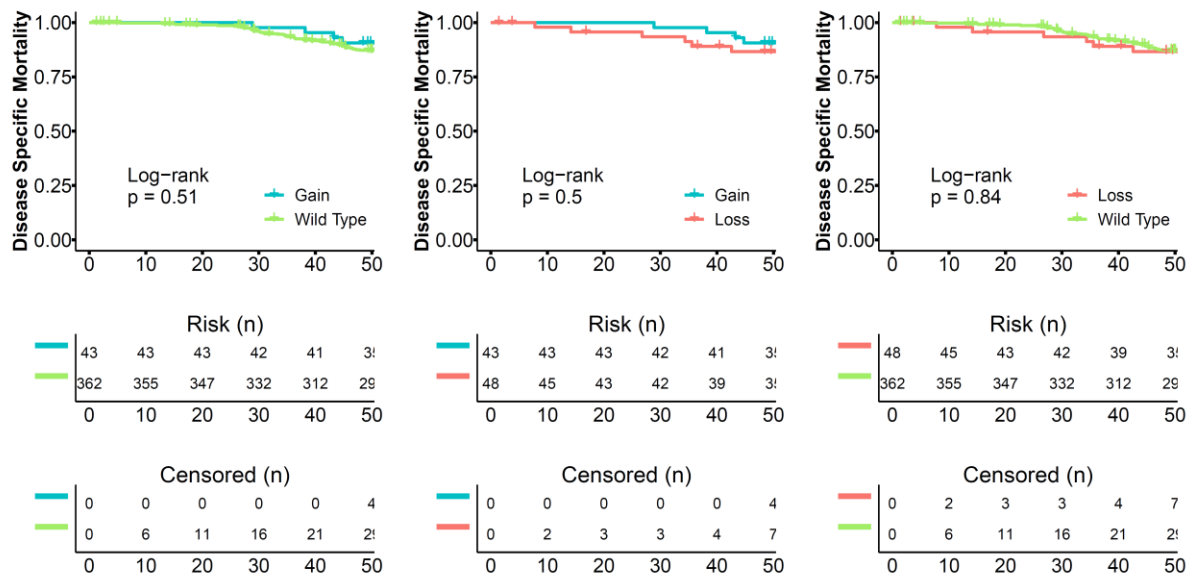

Figure 3.3.1C: In the Luminal B subtype, copy number changes of *PTPN11*/*SHP2* does not associate with any clinicopathological phenotype including (A) age, (B) tumor size, (C) grade, (D) stage, or (F) DSS except (E) lymph node status where patients with *PTPN11*/*SHP2* loss has more LN0 than the patients with wildtype copy of *PTPN11*/*SHP2*. Y-axis of C, D, E shows the fraction of patients.

3.3.1D: Clinical Correlation of *PTPN11*/*SHP2* copy number changes in HER2 Subtype:

Although in section 3.3.1A.2, *PTPN11*/*SHP2* copy number changes do not correlate to HER2 status, *PTPN11*/*SHP2* being a positive regulator of EGFR signaling (Agazie and Hayman 2003) were correlated to clinical parameters in the HER2 subtype. We do not observe a significant correlation of *PTPN11*/*SHP2* copy number variations to clinical parameters of HER2 subtype including age (A), tumor size (B), grade (C), stage (D), node status (E), and disease-specific mortality (F) in METABRIC cohort. Details of analysis provided in table 3.3.1D.

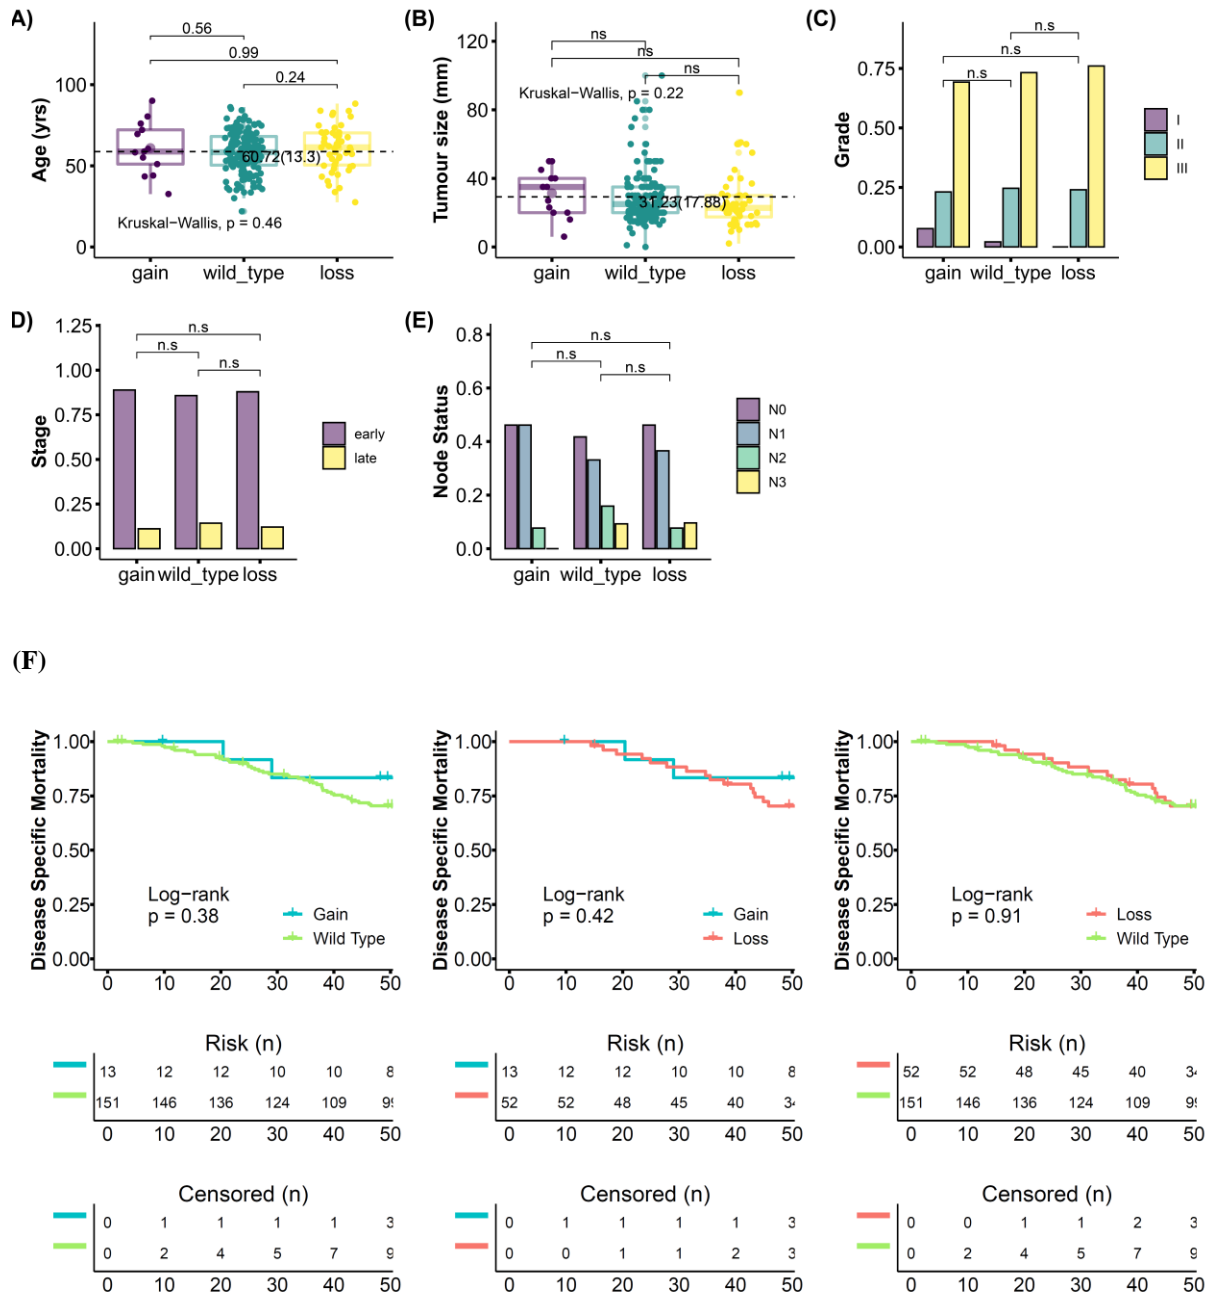

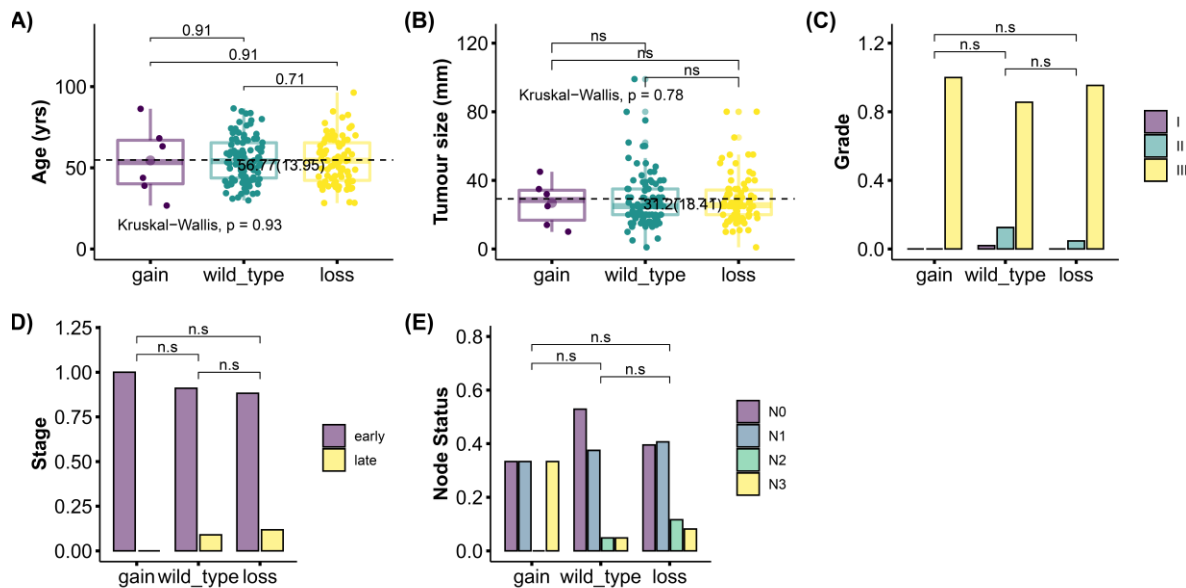

Figure 3.3.1D: In HER2 subtype, copy number changes of *PTPN11*/*SHP2* do not associate with any clinicopathological phenotype including (A) age, (B) tumor size, (C) grade, (D) stage, (E) lymph node status, and (F) DSS. Y axis of C, D, E shows the fraction of patients.

3.3.1E: Clinical Correlation of *PTPN11*/*SHP2* copy number changes in Basal Subtype:

In section 3.3.1A.2, *PTPN11*/*SHP2* copy number loss positively correlated to the Basal subtype. Alternatively, *PTPN11*/*SHP2* has been reported to help in the expression of receptor tyrosine kinases to promote the tumorigenic potential of BTBC (Mataalkah et al. 2016). We analyzed if *PTPN11*/*SHP2* copy number loss can function as a prognostic marker in the basal subtype. We do not observe a significant correlation between *PTPN11*/*SHP2* copy number variations and clinical parameters within basal subtype including age (A), tumor size (B), grade (C), stage (D), Node status (E), and 4 years disease-specific prognosis (F) in METABRIC cohort. Details of the analysis are provided in table 3.3.1E.

(F)

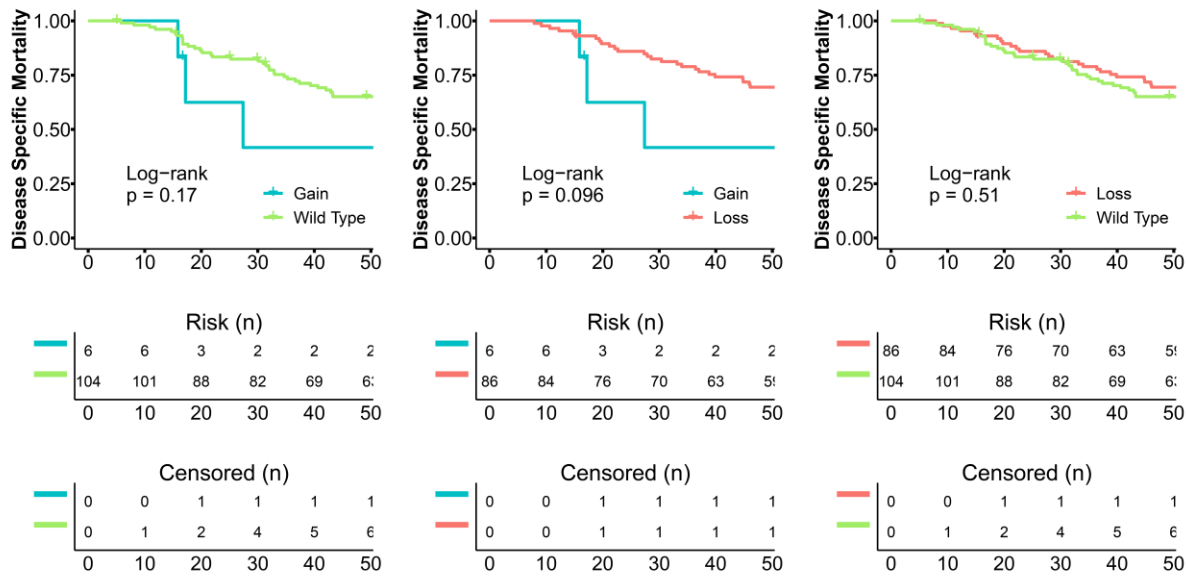

Figure 3.3.1E: In Basal subtype copy number changes of *PTPN11/SHP2* do not associate to any clinicopathological phenotype including (A) age, (B) tumor size, (C) grade, (D) stage, (E) lymph node status, and (F) DSS. Y-axis of C, D, E shows the fraction of patients.

3.3.1F: Clinical Correlation of *PTPN11/SHP2* copy number changes in *YAP1* high expression group of patients:

METABRIC cohort was divided into *YAP1* gene expression status to confirm observation from the *Drosophila* screen (Chapter 2). We grouped patients with *YAP1* gene expression above the 3rd quartile as *YAP1* high expressing group. Within *YAP1* high expressing patient group, *PTPN11/SHP2* copy number changes were correlated to clinical parameters to understand the effect of *PTPN11/SHP2* in *YAP1* driven breast cancers. There were no correlations regarding *PTPN11/SHP2* copy number changes and age (A), tumor size (B), stage (D), node status (E). However, patients with *PTPN11/SHP2* copy number loss correlated to grade 3 tumors at diagnosis (C) and 4 years DSS (F) in the *YAP1* high subset of the METABRIC cohort. Details of the analysis are provided in table 3.3.1F.

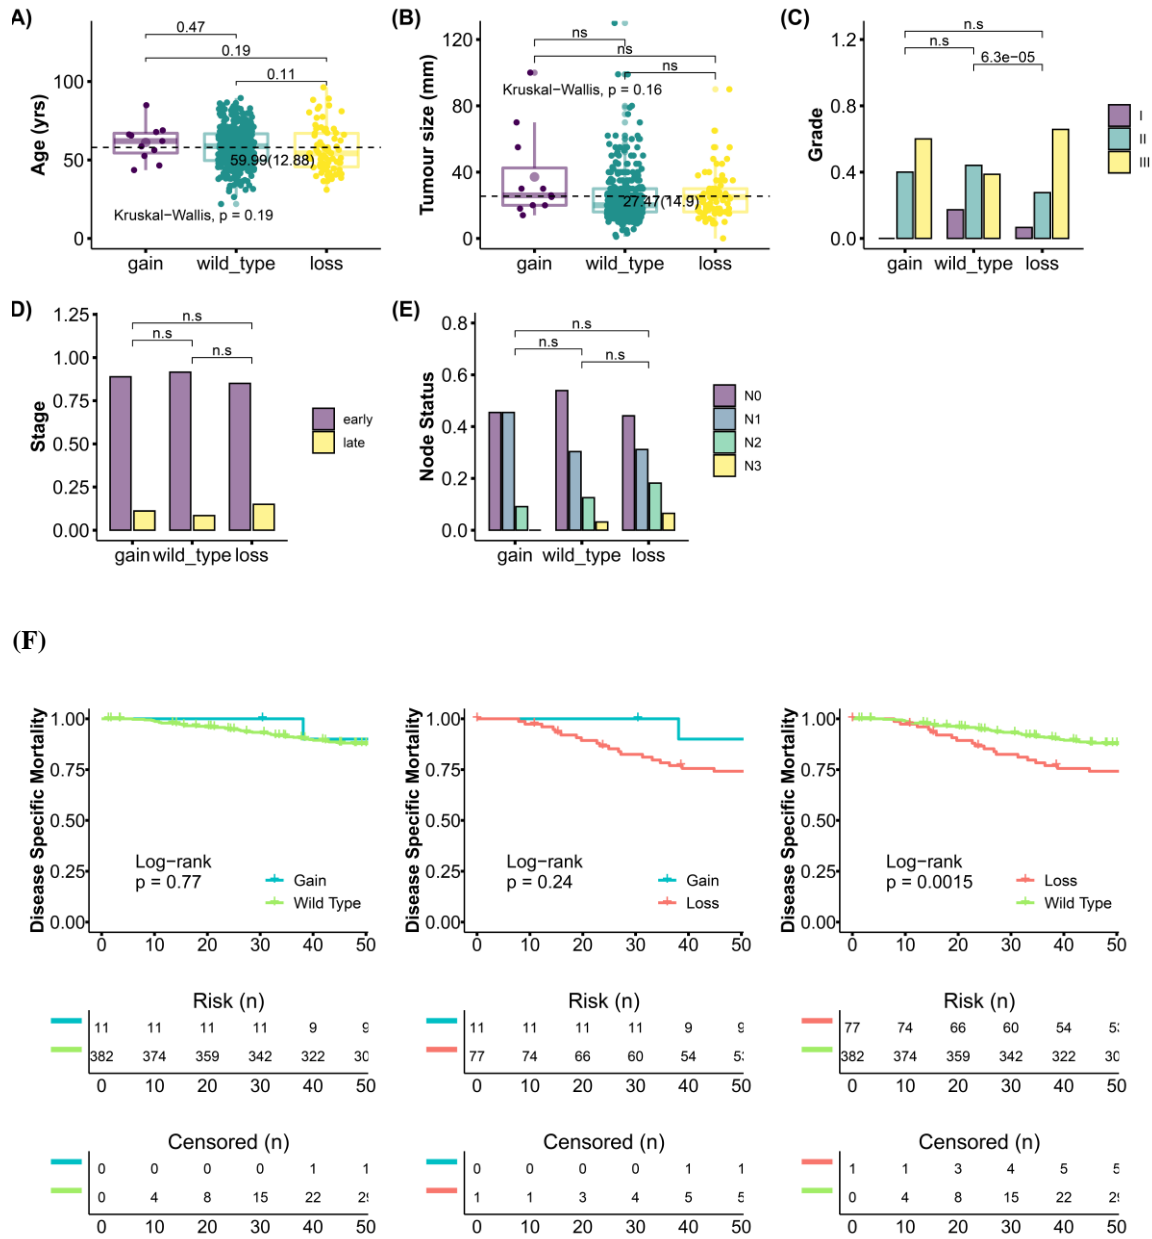

Figure 3.3.1F: In *YAP1* overexpressing breast cancer patients, we do not observe a significant correlation between *PTPN11/SHP2* copy number variations and (A) age, (B) tumor size, (D) stage, (E) Node status. However, (C) we observe *PTPN11/SHP2* copy number loss correlates to grade 3 tumors and (F) poor 4 years DSS. Y-axis of C, D, E shows the fraction of patients.

3.3.2A: Correlation of *PTPN11*/SHP2 copy number changes and clinical parameters of TCGA 2015 breast cancer patient cohort

3.3.2A.1: Clinical Correlation of *PTPN11*/SHP2 copy number changes and clinical parameters of patients at diagnosis:

Similar to the METABRIC cohort, we examined the statistical association of *PTPN11*/SHP2 copy number changes and clinical parameters in the TCGA BRCA cohort. We looked at correlations to age, tumor size, lymph node status, and stage to identify the tumorigenic role of *PTPN11*/SHP2 in breast cancer. We did not look at the survival of the TCGA BRCA cohort because of poor follow up data in the TCGA cohort.

Our analysis suggests, *PTPN11*/SHP2 copy number changes significantly correlate to its gene expression pattern (A). However, we do not observe a significant association between *PTPN11*/SHP2 copy number variations and clinical parameters including age (B), tumor size (C), node status (D), and stage (E) of BRCA TCGA cohort. Details of analysis provided in table 3.3.2A.1.

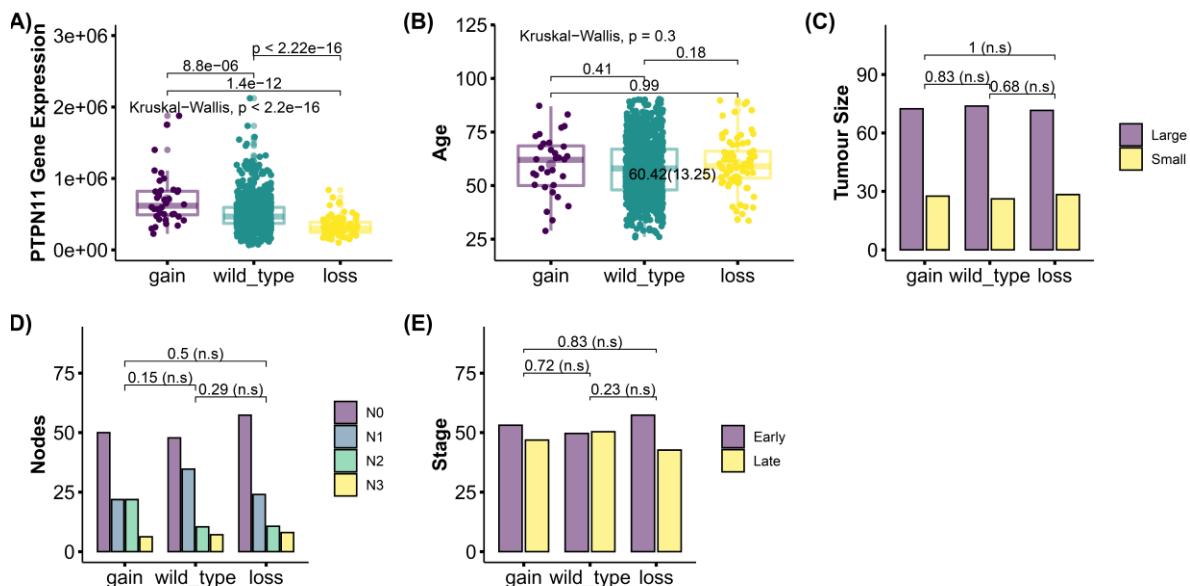

Figure 3.3.2A.1: (A) shows *PTPN11*/SHP2 copy number changes significantly correlate to the *PTPN11* gene expression pattern as obtained from RNA-seq data. Copy number changes of

PTPN11/SHP2 does not associate with any clinicopathological parameter including (B) age, (C) tumor size, (D) node, (E) stage in total TCGA 2015.

3.3.2A.2: Clinical Correlation of *PTPN11*/SHP2 copy number changes and molecular subtype of patients at diagnosis:

We verified if *PTPN11*/SHP2 copy number variations correlate to any particular subtype like in the METABRIC cohort. We do not observe any significant associations between *PTPN11*/SHP2 copy number variations to ESR1 expression (A), however, we see *PTPN11*/SHP2 copy number loss correlate to low YAP1 expression (B). There was no association of *PTPN11*/SHP2 copy number variations to any other PAM50 subtype (C) in the TCGA cohort. Alternatively, there was no association of Luminal A (D) or Luminal B (E) HER2 (F), and Basal (G) subtype to *PTPN11*/SHP2 copy number changes. Details of analysis provided in table 3.3.2A.2.

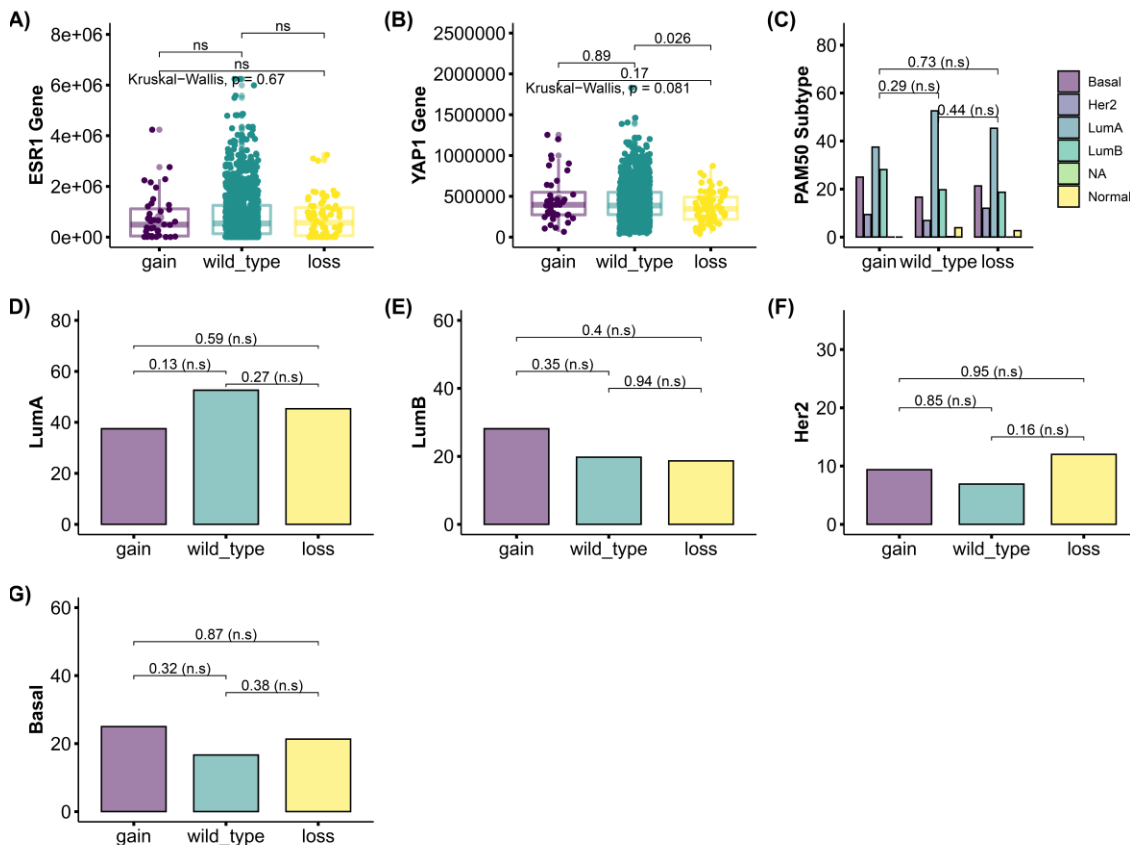

Figure 3.3.2A.2: (A) shows copy number variations of *PTPN11*/SHP2 does not associate with ESR1 expression. (B) shows *PTPN11*/SHP2 copy number loss associate with lower YAP1

expression. (C) shows copy number variations of *PTPN11*/*SHP2* does not associate with any other PAM50 subtype. There was no significant association to subtype as seen in (D) correlation of Luminal A, (E) correlation of Luminal B, (F) correlation of HER2 subtype, and (G) correlation of basal subtype to copy number changes of *PTPN11*/*SHP2*.

3.3.2B: Clinical Correlation of *PTPN11*/*SHP2* copy number changes in Luminal A Subtype:

We did not observe any associations of *PTPN11*/*SHP2* copy number variations to clinical phenotype. To identify if *PTPN11*/*SHP2* has any subtype-specific role, *PTPN11*/*SHP2* copy number variations were correlated to clinical parameters within the Luminal A subtype. We do not observe a significant association of *PTPN11*/*SHP2* copy number variations and age (A), tumor size (B), node status (C), metastasis (D), and stage (E) in the Luminal A subtype of BRCA TCGA cohort. Details of analysis provided in table 3.3.2B.

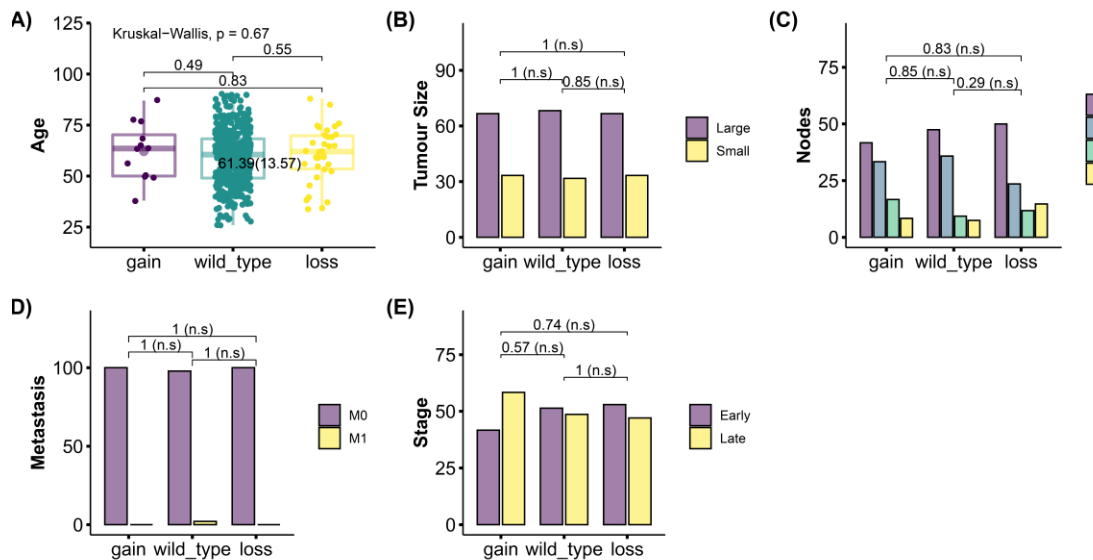

Figure 3.3.2B: Within Luminal A subtype of TCGA cohort, copy number changes of *PTPN11*/*SHP2* do not associate with any clinicopathological phenotype including (A) age, (B) tumor size, (C) nodes positivity, (D) metastasis, and (E) stage.

3.3.2C: Clinical Correlation of *PTPN11*/*SHP2* copy number changes in Luminal B Subtype:

PTPN11/*SHP2* copy number variations were also correlated to clinical parameters within the Luminal B subtype to identify any subtype-specific role of *PTPN11*/*SHP2*. We do not observe any significant correlation of *PTPN11*/*SHP2* copy number variations and clinical parameters including age (A), tumor size (B), node status (C), metastasis (D), and stage (E) in the Luminal B subtype of BRCA TCGA cohort. Details of analysis provided in table 3.3.2C.

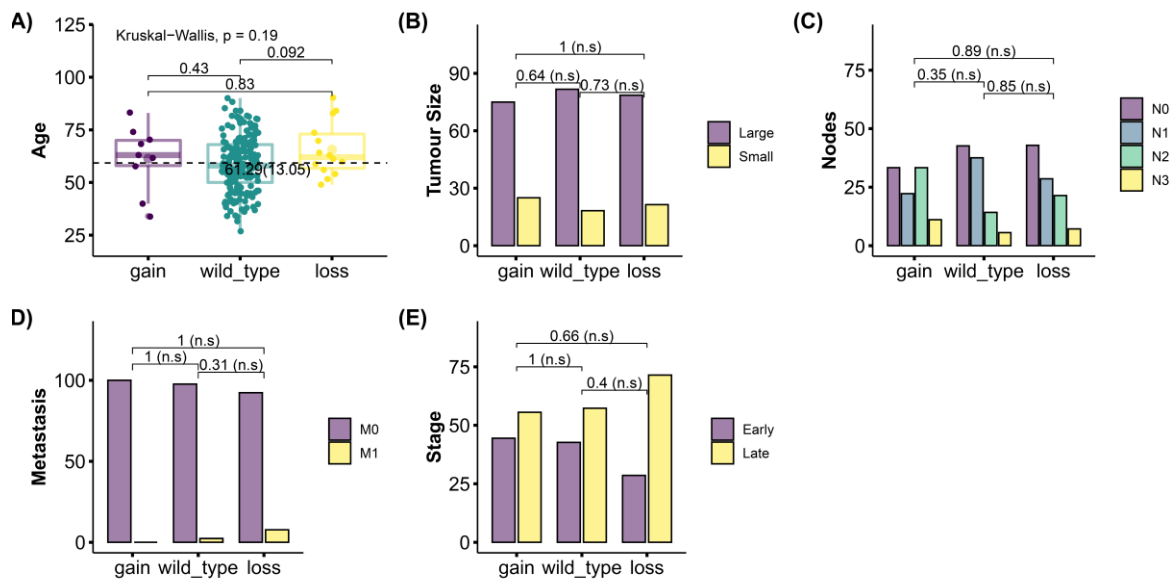

Figure 3.3.2C: In the Luminal B subtype, *PTPN11*/*SHP2* copy number changes do not associate with any clinicopathological phenotype including (A) age, (B) tumor size, (C) node status, (D) metastasis, and (E) stage.

3.3.2D: Clinical Correlation of *PTPN11*/*SHP2* copy number changes in HER2 Subtype:

PTPN11/*SHP2* copy number variations were correlated to clinical parameters within the HER2 subtype to examine its role in EGFR driven neoplasia. We do not observe a significant correlation of *PTPN11*/*SHP2* copy number variations and clinical parameters like age (A), tumor size (B), node status (C), metastasis (D), and stage (E) of the HER2 subtype of BRCA TCGA cohort. Details of analysis provided in table 3.3.2D.

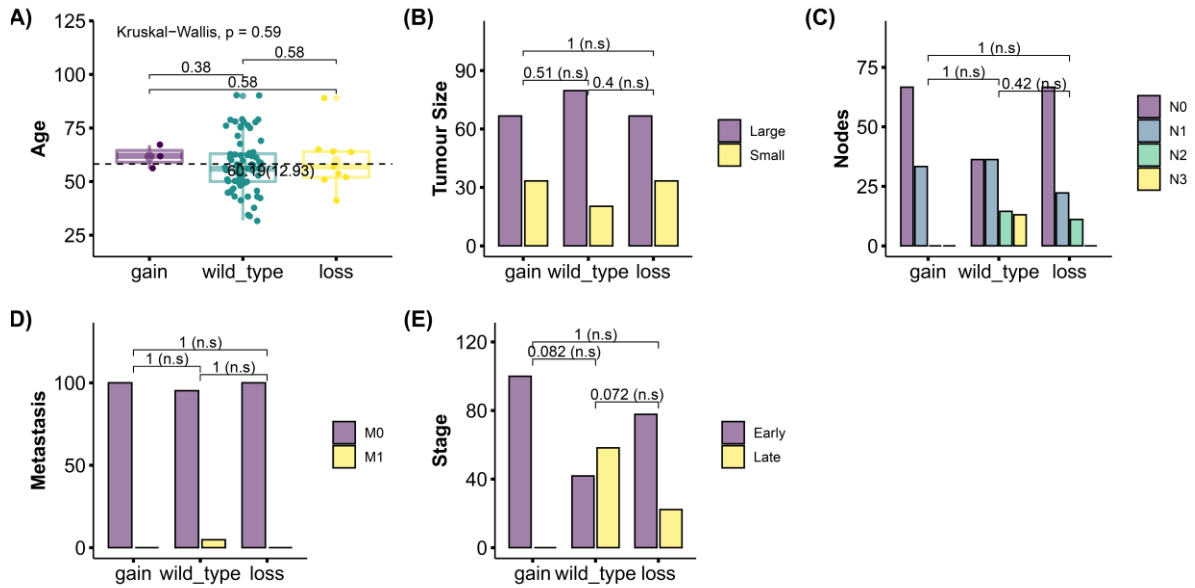

Figure 3.3.2D: In HER2 subtype, copy number changes of *PTPN11/SHP2* do not associate with any clinicopathological phenotype including (A) age, (B) tumor size, (C) lymph node status, (D) metastasis, and (E) stage.

3.3.2E: Clinical Correlation of *PTPN11/SHP2* copy number changes in Basal Subtype:

PTPN11/SHP2 copy number variations were correlated to clinical parameters within the basal subtype. We do not observe a significant correlation between *PTPN11/SHP2* copy number changes and clinical parameters including age (A), tumor size (B), node status (C), metastasis (D), and stage (E) in the Basal subtype of BRCA TCGA cohort. Details of analysis provided in table 3.3.2E.

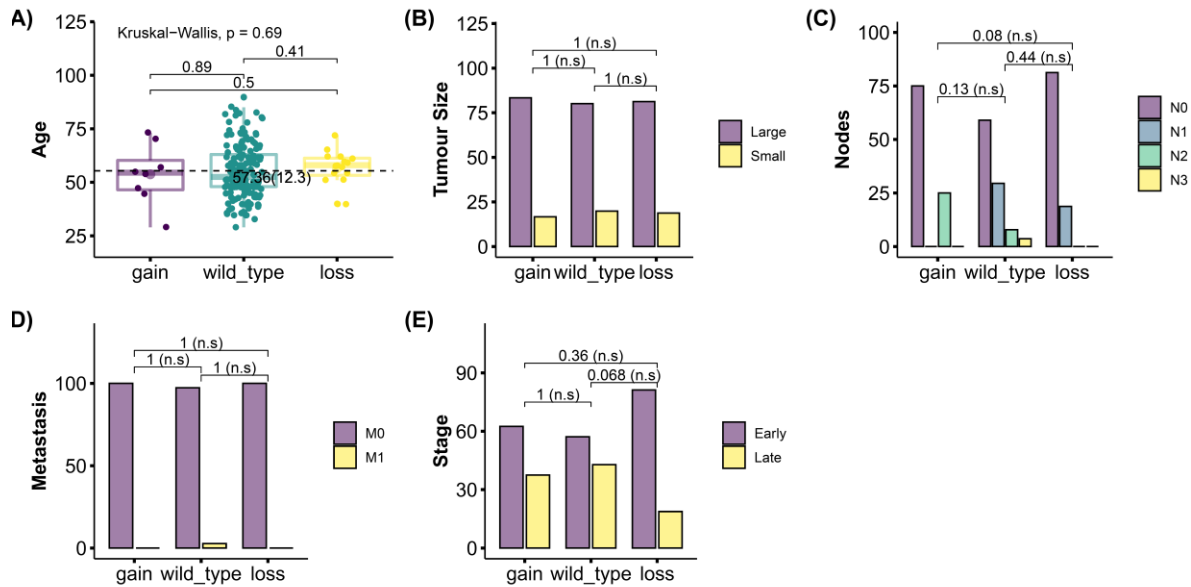

Figure 3.3.2E: In the Basal subtype, copy number changes of *PTPN11*/*SHP2* do not associate with any clinicopathological phenotype including (A) age, (B) tumor size, (C) node status, (D) metastasis, and (E) stage.

3.3.2F: Clinical Correlation of *PTPN11*/*SHP2* copy number changes in *YAPI* high expression group of patients:

We have observed in section 3.3.2A.2, *PTPN11*/*SHP2* copy number loss in TCGA correlates to low *YAPI* expression. To understand the clinical role of *PTPN11*/*SHP2* copy number changes in the *YAPI* high subgroup of TCGA BRCA patients we looked into the association of copy number changes and clinical parameters within the *YAPI* high subset of patients (*YAPI* gene expression above the third quartile). We do not observe a significant correlation between *PTPN11*/*SHP2* copy number variations and age (A), tumor size (B), node status (C), metastasis (D), and stage (E) in the *YAPI* high subset of the BRCA TCGA cohort unlike observed in METABRIC cohort. Details of analysis provided in table 3.3.2F.

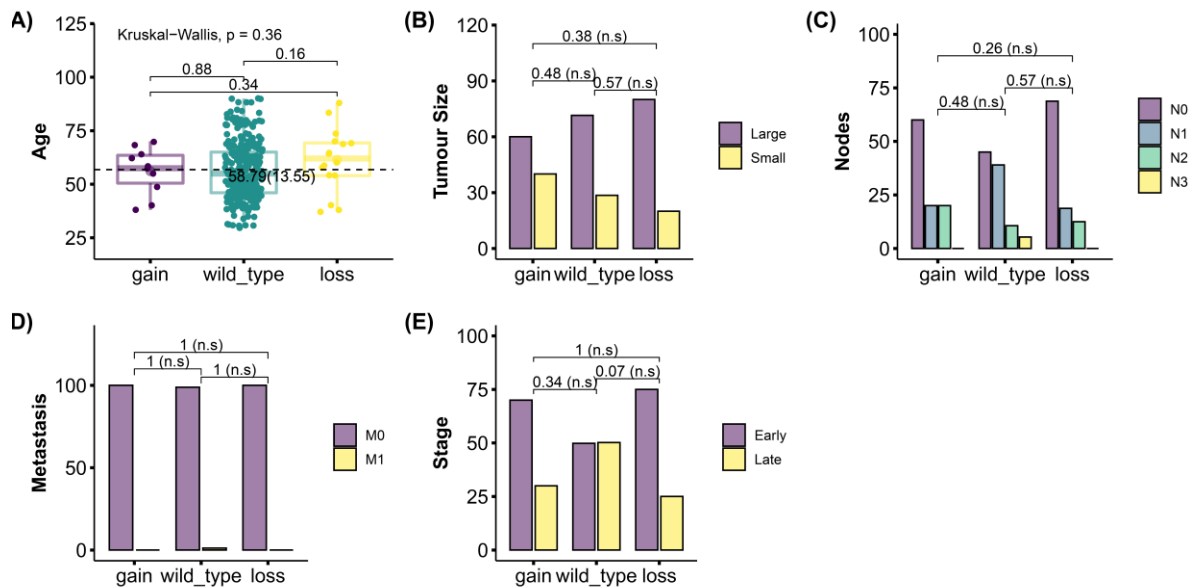

Figure 3.3.2F: In *YAP1* high subtype, copy number changes of *PTPN11/SHP2* do not associate with any clinicopathological phenotype including (A) age, (B) tumor size, (C) node status, (D) metastasis, and (E) stage.

3.3.2G: Clinical Correlation of Phospho (tyrosine 542) *PTPN11/SHP2* protein expression to the clinical phenotype of patients at diagnosis:

PTPN11/SHP2 is a phosphatase and TCGA provides RPPA data of around 225 protein and phosphoproteins. Phospho SHP2-Y542 is the active form of the phosphatase. In our study, we report for the first time, the association of active *PTPN11/SHP2* to clinicopathological parameters and understand the effect of *PTPN11/SHP2* phosphatase in tumorigenesis. Phospho SHP2 Y542 protein expression was correlated to clinical parameters in total BRCA patients using level 4 RPPA data from TCGA 2015. We do not observe a significant correlation between phospho SHP2 Y542 protein expression and age (A). However, low expression of phospho SHP2-Y542 correlates to larger tumor size (B), more N2 positivity (C), late-stage cancer (E), and luminal subtype of breast cancer (F). There was no significant correlation between metastasis and active protein (D).

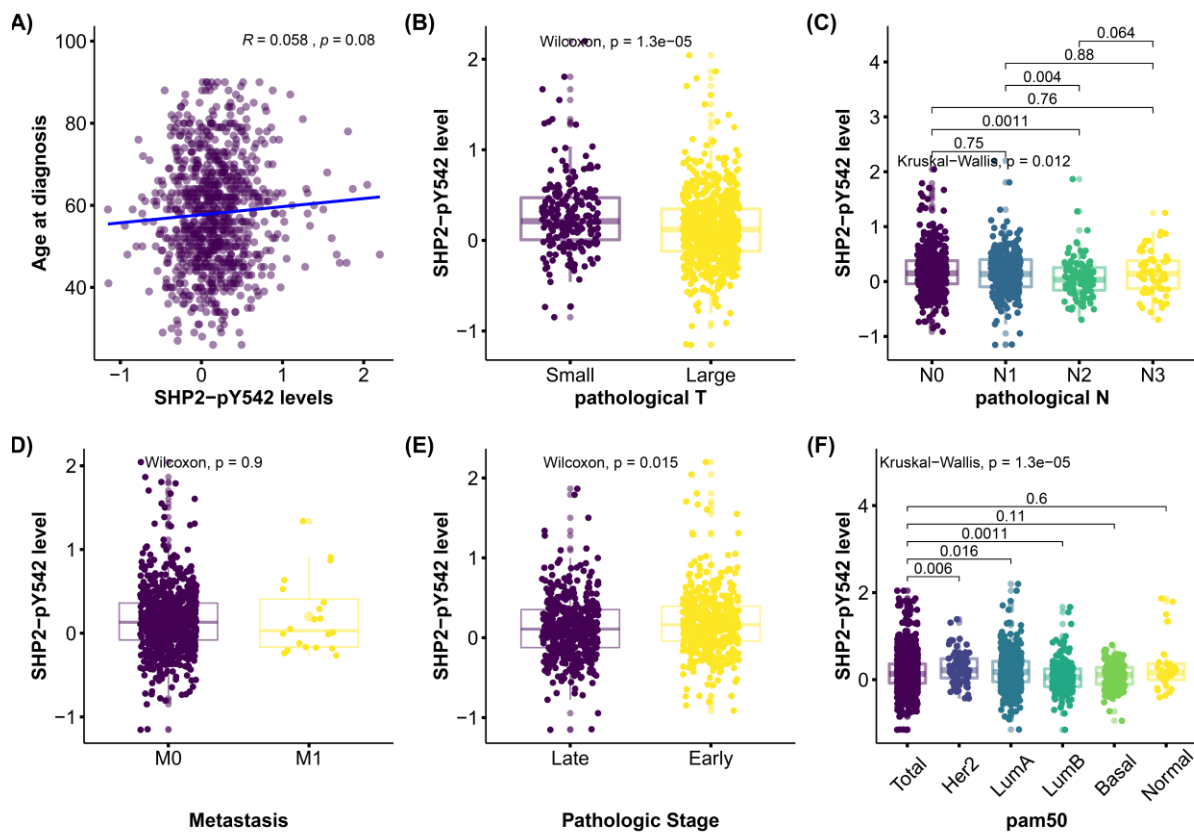

Figure 3.3.2G: (A) shows phosphorylated SHP2 Y542 does not associate with the age of onset of breast cancer disease or (D) to metastasis. However, (B) low expression levels of Phospho SHP2 Y542 significantly associates with larger tumor size, (C) LN2 positivity, (E) late-stage cancer, and (F) specificity to a Luminal subtype of breast cancer at diagnosis.

3.3.2H: Clinical Correlation of Phospho (tyrosine 542) *PTPN11*/SHP2 protein expression to the clinical phenotype of Luminal A patients at diagnosis:

To re-confirm our observation in section 3.3.1B, if *PTPN11*/SHP2 positively correlates to the aggressive nature of Luminal A cancer, phospho SHP2 Y542 protein expression was correlated to the luminal subtype of patients. We grouped patients into two groups, expressing high (above 3rd quartile) and low (below 1st quartile) levels of phospho SHP2 Y542. We correlated clinical parameters within the Luminal A subtype of BRCA patients to phospho SHP2 Y542 subsets. We do not observe a significant correlation between phospho SHP2 Y542 protein expression and age

(A), metastasis (E), and stage (F). However, low expression of phospho SHP2-Y542 protein correlates to low *YAP1* gene expression (B), larger tumor size (C), more N2/N3 positivity (D) in the luminal A subtype of breast cancer. Details of analysis in table 3.3.2H. In summary, our RPPA data analysis suggests a similar trend as observed in the METABRIC cohort, low expression of phospho SHP2 Y542 associates with aggressive tumors at diagnosis, and might behave as a putative tumor suppressor in Luminal A subtype of patients.

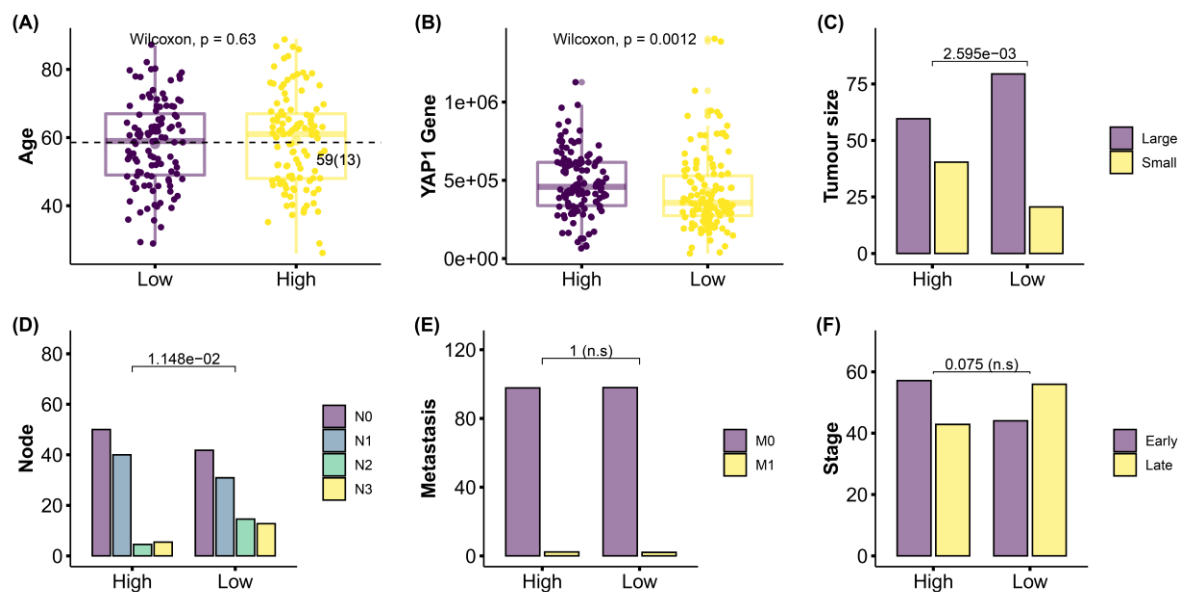

Figure 3.3.2H: In Luminal A subtype, (A) phospho SHP2 Y542 does not associate with the age of patients at diagnosis, (E) the number of metastasized sites, and (F) stage of cancer. However, (B) phospho Y542 *PTPN11*/SHP2 expression shows a negative association with *YAP1* expression, (C) larger tumor size, (D) LN2 and LN3 positivity as compared to high phospho SHP2 Y542 expression.

3.3.2I: Clinical Correlation of Phospho (tyrosine 542) *PTPN11*/SHP2 protein expression to the clinical phenotype of Luminal B patients at diagnosis:

Likewise, phospho SHP2 Y542 protein expression was also correlated to clinical parameters in the Luminal B subtype of BRCA patients using level 4 RPPA data from TCGA 2015. We do not observe a significant correlation of phospho SHP2 Y542 protein expression with age (A), larger

tumor size (C), metastasis (E), and stage (F). However, Phospho (tyrosine 542) *PTPN11*/SHP2 protein expression positively correlates to *YAP1* gene expression (B) and N3 positivity (D) in the luminal B subtype. Details of analysis in table 3.3.2I. In Summary, copy number analysis from the METABRIC cohort (section 3.3.1C) together with the phosphoprotein study in TCGA, *PTPN11*/SHP2 might function pro-tumorigenic in the Luminal B subtype of breast cancer patients.

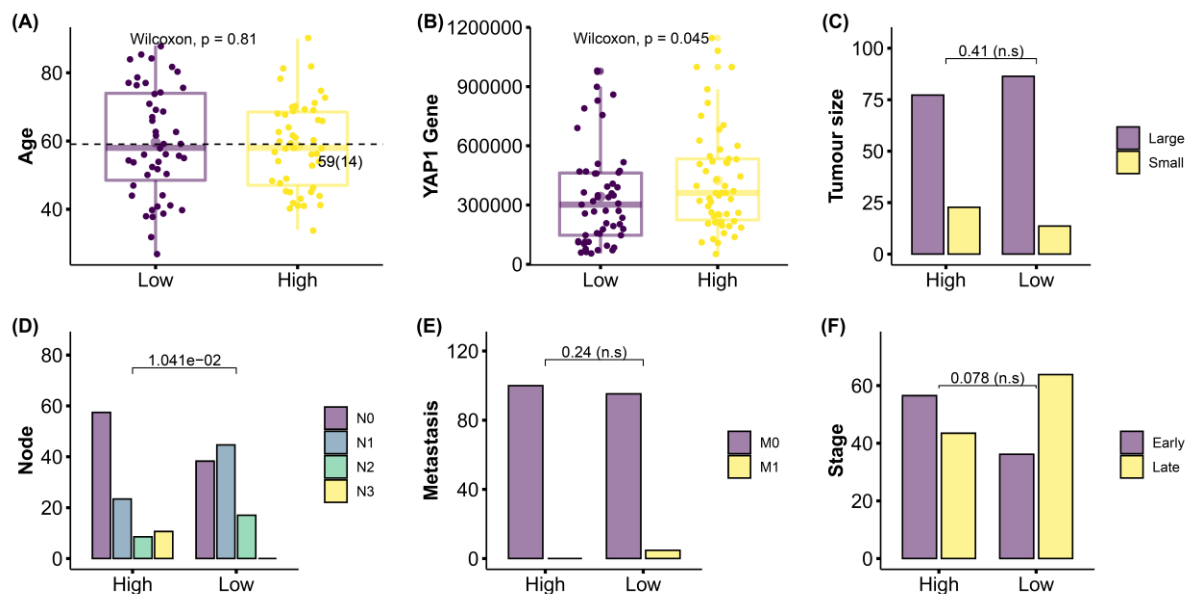

Figure 3.3.2I: In the Luminal B subtype, (A) phospho SHP2 Y542 does not associate with the age of patients at diagnosis. (B) Expression of *YAP1* and phospho SHP2 Y542 show a positive correlation. However, (C) phospho SHP2 Y542 expression levels do not associate with any clinical parameter including tumor size, (E) the number of metastasized sites, and (F) stage of cancer at diagnosis. (D) shows Phospho SHP2 Y542 shows a positive correlation to lymph node positivity.

3.3.2J: Clinical Correlation of Phospho (tyrosine 542) *PTPN11*/SHP2 protein expression to the clinical phenotype of HER2 patients at diagnosis:

PTPN11/SHP2 is a positive regulator of EGFR/HER2 signaling, we assessed the same using TCGA phosphoprotein data of *PTPN11*/SHP2 in the HER2 subtype of BRCA patients. We do not

observe any significant correlation between phospho SHP2 Y542 and age (A), *YAP1* gene expression (B), larger tumor size (C), node positivity (D), metastasis (E), and stage (F). In summary, we re-confirmed our observation from METABRIC in TCGA, *PTPN11*/SHP2 does not associate significantly with HER2 to co-operate in tumorigenesis.

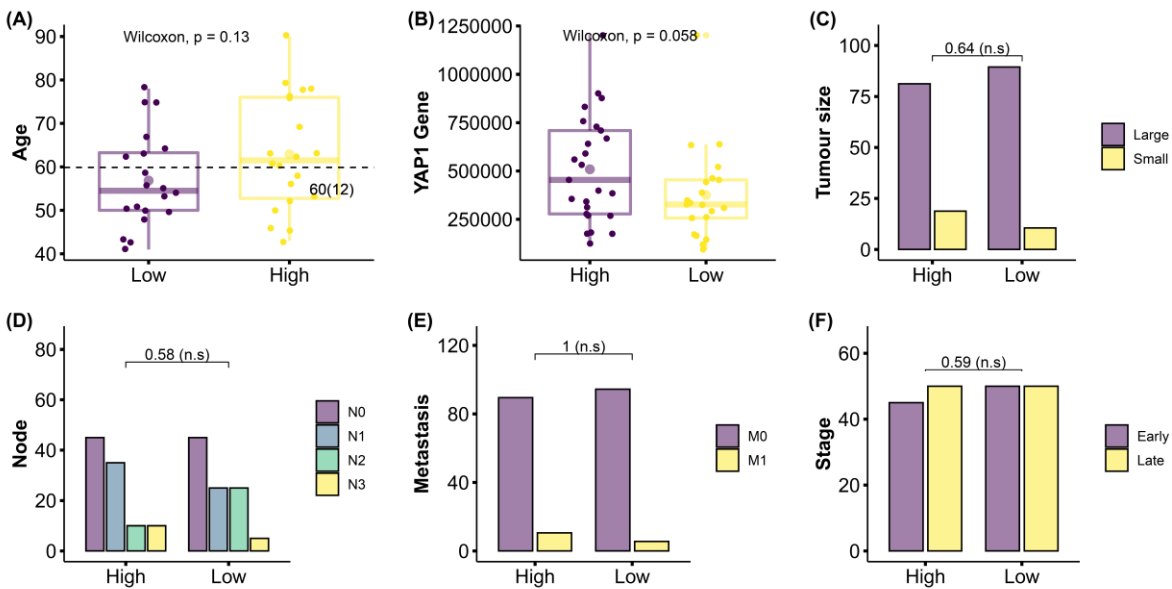

Figure 3.3.2J: In HER2 subtype, phospho SHP2 Y542 expression does not associate with any clinical parameter including (A) age, (B) *YAP1* gene expression, (C) larger tumor size, (D) node positivity, (E) metastasis, and (F) stage.

3.3.2K: Clinical Correlation of Phospho (tyrosine 542) *PTPN11*/SHP2 protein expression to the clinical phenotype of Basal patients at diagnosis:

Phospho SHP2 Y542 expression was correlated to clinical parameters in the Basal subtype of BRCA patients using level 4 RPPA data from TCGA 2015 to identify its prognostic effect in the Basal subtype of breast cancer. We do not observe a significant correlation between Phospho SHP2 Y542 expression and age (A), larger tumor size (C), node positivity (D), metastasis (E), and stage (F). However, Phospho SHP2 Y542 expression shows a positive correlation to *YAP1* gene expression (B).

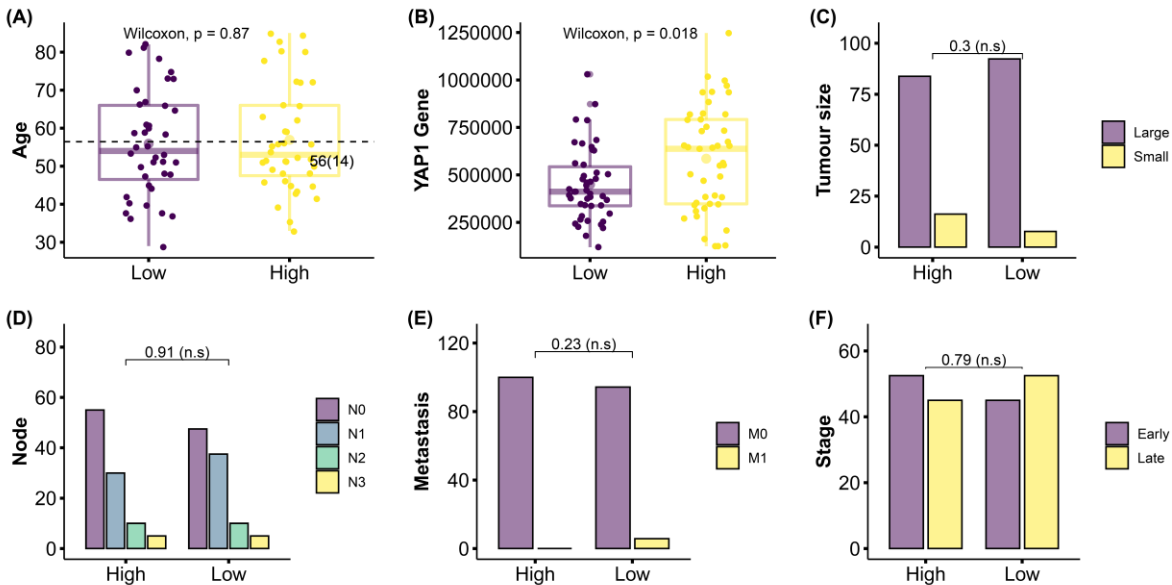

Figure 3.3.2K: In Basal subtype, (B) *YAP1* and phospho Y542 *PTPN11/SHP2* are positively correlated. Phospho Y542 *PTPN11/SHP2* expression does not associate with any clinical parameter including (A) age, (B) tumor size, (C) node positivity, (E) metastasis, and (F) stage.

3.4: Discussion

The results of our analysis of the METABRIC dataset show loss of *PTPN11/SHP2* correlate to the early onset of breast cancer disease at least in the UK/Canadian cohort. We observe patients with *PTPN11/SHP2* copy number loss are diagnosed with grade 3 and late-stage cancer at diagnosis with poor 4 years OS and DSS in the METABRIC cohort. Furthermore, we find *PTPN11/SHP2* copy number loss correlates to low ER expression and low frequency of ER subtype. Within the Luminal A subtype, *PTPN11/SHP2* copy number loss correlates to late-stage cancer and poor 4 years of disease-specific survival. Interestingly, copy number loss of *PTPN11/SHP2* correlates to lesser lymph node positivity. In our study, we report *PTPN11/SHP2* functions like a putative tumor suppressor precisely in the Luminal A subtype and as protumorigenic in the Luminal B subtype of breast cancer patients in the METABRIC cohort.

Analysis of the TCGA dataset independently suggested *PTPN11/SHP2* copy number variations do not correlate to any clinical parameters in the total breast cancer dataset. However, analysis of phosphoprotein expression suggested a similar trend observed in our METABRIC study.

PTPN11/SHP2 being a phosphatase, we report for the first time, correlation of its active phosphorylated protein expression to clinical parameters using TCGA RPPA 2015 data in breast cancer. We observe active *PTPN11*/SHP2 indeed functions as a tumor suppressor, wherein low activity of *PTPN11*/SHP2 associates to more aggressive tumors at diagnosis with larger tumor size and LN2 positivity and lower expression in the Luminal subtype in the total TCGA dataset. Moreover, when we analyse specific subtype and correlate active *PTPN11*/SHP2 expression groups to clinical parameters, we observed low expression of phospho SHP2 Y542 associates with larger tumor size and greater lymph node positivity suggesting its plausible tumor suppressor role in the Luminal A subtype. Contrarily, phospho SHP2 Y542 expression positively correlates to lymph node positivity and suggestive of its pro-tumorigenic role in the Luminal B subtype. This is in agreement with our observation in the METABRIC cohort.

The oncogenic function of *PTPN11*/SHP2 has been reported in the backgrounds of HER2, EGFR, and PI3K-AKT in breast cancer (Aceto et al. 2012; K. Zhang et al. 2016). We report from our analysis using two independent cohorts, *PTPN11*/SHP2 does not show any strong associations in co-operating with HER2 driven breast cancer.

PTPN11/SHP2 was also reported to promote TNBC by mediating crosstalk between EGFR and wnt signaling (Aceto et al. 2012), while inhibition of *PTPN11*/SHP2 has been reported to promote basal to luminal A transition (H. Zhao and Agazie 2015). Our analysis suggests *PTPN11*/SHP2 does not associate with the Basal subtype.

In the context of *YAP1* driven cancer, *PTPN11* ortholog Csw functions as a tumor suppressor in *Yki* overexpressing epithelial discs. Clinical data suggest a strong association between *YAP1* and *PTPN11*/SHP2 expression at least in the METABRIC cohort. We looked into *YAP1* overexpressing subtype, a known oncogene in breast cancer. We report *PTPN11*/SHP2 loss is inversely correlated to *YAP1* expression in the METABRIC cohort. Furthermore, in the *YAP1* high expressing a subset of METABRIC patients, we observe a loss of *PTPN11*/SHP2 associate with grade 3 tumors and poor 4 years DSS. However, we do not observe any association with any clinical parameter in the *YAP1* high expressing subtype of patients in the TCGA cohort. However, *YAP1* functions as a putative tumor suppressor in the luminal subgroup of breast cancer patients (Cao, Sun, and Yao 2017; Lehn et al. 2014). Hence it will be interesting to investigate the role of *PTPN11*/SHP2 in *YAP1* driven breast tumorigenesis.

The functional duality of molecules like kinases and phosphatases in cancer is a challenging area for cancer treatment and targeted therapeutic courses. We report in our study patients with loss or low activity of *PTPN11*/SHP2 is diagnosed with an aggressive tumor, however, *PTPN11*/SHP2 does not seem to behave like an ideal tumor suppressor candidate from our analysis. Since it is a phosphatase it can function in a dose-dependent manner. Suboptimal levels above wildtype such as gain of copy number could allow it to behave differently, depending on upstream molecular cues/context. Loss of function genetics could be a valuable tool to understand its intrinsic behaviour. Its role in the context of the YAP1 background also needs further elucidation.

Chapter 4: Function of *PTPN11*/SHP2 in tumorigenesis of breast epithelial cells

4.1.1: Introduction

Src homology phosphatase 2 (SHP2) encoded by the *PTPN11* gene is one of the few phosphatases to function as an oncogene (S. Zhao, Sedwick, and Wang 2015). *PTPN11*/SHP2 has two N terminal SH2 domains, N-SH2 and C-SH2, a middle phosphatase domain, and a C terminal proline-rich tail with tyrosine 542 and 580 phosphorylated by Src Kinases (Neel, Gu, and Pao 2003; S. Zhao, Sedwick, and Wang 2015). Characterization of phosphorylation profile regulated by *PTPN11*/SHP2 activity and its localization has identified 53 different proteins including ERK, P38, and many adhesion kinases (Corallino et al. 2016). Among other bonafide targets, *PTPN11*/SHP2 is known to facilitate dephosphorylation of B catenin and enable VE-Cadherin recovery at adheren junctions of endothelial cells (Timmerman et al. 2012). Furthermore, *PTPN11*/SHP2 targets Tyr117 of Vimentin and prevent lamellipodia formation and cell migration in MEFs and NIH3T3 cells (Yang et al. 2019). Besides, *PTPN11*/SHP2 also promotes Tks5 dephosphorylation in Src transformed Mouse Embryonic Fibroblast (MEFs) and NIH3T3 to reduces podosome rosette formation and cell migration (Y. R. Pan et al. 2013).

In the context of cell cycle regulation, depletion of *PTPN11*/SHP2 interferes with checkpoint kinase 1 (CHK1) activation and delay in both Cyclin E accumulation and G1-S arrest (Tsang et al. 2012). Moreover, catalytically active *PTPN11*/SHP2 modulates Polo-like Kinase 1 (PLK1) and Aurora B activity to regulate chromosomal alignment, restoring checkpoint function at metaphase (Liu, Zheng, and Qu 2012). Alternatively, kinase-inactive *PTPN11*/SHP2 is involved in regulating the nuclear Cell Division Cycle (CDC) 25C translocation to the cytoplasm through 14-3-3 β and inducing G2-M arrest (L. Yuan et al. 2005).

In response to DNA damage, the phosphatase activity of nuclear *PTPN11*/SHP2 is shown to be enhanced in embryonic fibroblast cells to activate c-Abl kinase via its SH3 domain which stabilizes P73 and allow transcription of target genes including P21^{Cip1} and initiate apoptosis (L.

Yuan et al. 2003). Besides, *PTPN11*/SHP2 along with Protein Tyrosine Phosphatase 1B (PTP-1B) and Phosphatase and Tensin homolog (PTEN) has been reported to mediate Rb/E2F associated apoptosis possibly by caspase8 and caspase3 activation (Morales et al. 2014).

The tumor suppressor role of *PTPN11*/SHP2, if any, has been recently reported in hepatocellular cancer (Bard-Chapeau et al., 2011) and oesophageal squamous cell cancer (Qi et al., 2017) by dephosphorylation of the phosphorylated Signal Transducer and Activator of Transcription factor 3 (pSTAT3). In the context of breast cancer, *PTPN11*/SHP2 functions as an oncogene by repressing let-7 miRNAs in HER2 overexpressing breast epithelial cells (Aceto et al. 2012).

4.1.2: Literature survey of the role of *PTPN11*/SHP2 upon DNA damage

We also looked into the publicly available literature on the role of *PTPN11*/SHP2 in DNA Damage in various cell systems. In our understanding, cell cycle checkpoint activation and cell cycle arrest are tightly regulated processes and involves a myriad of kinases: Ataxia telangiectasia (ATM) /ATM and Rad3 related (ATR), c-Abl, CHK1/CHK2, and P38 and phosphatases like Cdc25A, Cdc25B, Cdc25C, and Wee1-Myelin Transcription Factor 1 (MYT1) (Bulavin, Amundson, and Fornace 2002). Cdc25A functions mostly during early to late G1 along with Cdc25B and Cdc25C and allows S-phase entry by promoting dephosphorylation and activation of CDK2-CyclinE and Cyclin-Dependent Kinase (CDK) 2-Cyclin A complexes; Cdc25A, Cdc25B, and Cdc25C cooperate to promote mitotic entry by dephosphorylating and activating CDK1-CyclinB during G2-M transition (Boutros, Dozier, and Ducommun 2006). Upon DNA damage in the G1-S phase in HeLa cells, Phospho SHP2-Y542 induces CHK-1 Ser 317 phosphorylation by an unknown mechanism and helps in G1-S arrest and DNA repair (Tsang et al. 2012). Alternatively, SHP2 also helps in cell cycle arrest at the G2-M phase of the cell cycle in a catalytically independent manner as inactive SHP2 C459S was able to prevent nuclear translocation of Cdc25C and inhibit mitotic entry (L. Yuan et al. 2005).

Exposure to genotoxic stress later in the cell cycle, ATM activates P38 and CHK1 / CHK2; besides P38 phosphorylates Cdc25B and Cdc25C at Ser309 and Ser216 respectively (Han and Sun 2007). In an independent study, CHK1 is reported to phosphorylate Ser216 residue of Cdc25C and create a docking site of 14-3-3 β that allows Cdc25C and 14-3-3 β interaction and translocation to the cytoplasm, preventing entry into mitosis (Peng et al. 1997). *PTPN11*/SHP2 constitutively associates with 14-3-3 β and helps in this G2-M arrest upon DNA damage by stabilizing the

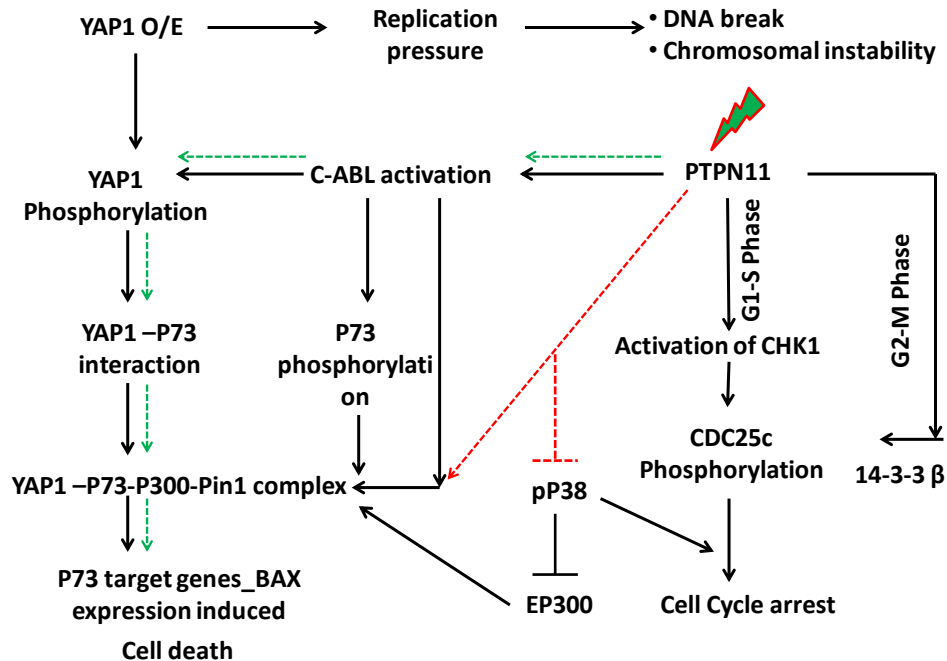

interaction between Cdc25c and 14-3-3 β in embryonic fibroblast immortalized by SV-40 T antigen (L. Yuan, Yu, and Qu 2003).

Extracellular signal Regulated Kinase (ERK) 1/2 activity is known to induce apoptosis in P53 independent manner but ATM-dependent manner by upregulating p21^{cip} genes (Tang et al. 2002). Yuan, Yu, & Qu, 2003 also showed p38 activity did not affect G2-M arrest in wild type but alters G2-M arrest in SHP2 Δ/Δ cells. The role of P38 in DNA damage has been independently studied, p38 allows AKT mediated phosphorylation of E1 associated Protein 300 (EP300) at Ser 1834 as observed in normal human fibroblast to enable acetylation of DNA lesions which relaxes the DNA around these lesions and let DNA repair genes recognize the damage followed by subsequent degradation of EP300 and recruitment of nucleotide excision repair machinery at the site of damage (Wang et al. 2013). We hypothesize *PTPN11*/SHP2 controls p38 activation and EP300 stabilization, knockdown of *PTPN11*/SHP2 allows degradation of EP300 and hence its target P73 and inhibits cell death.

Alternately, during DNA damage, *PTPN11*/SHP2 suggested to promote c-Abl activation, such that the deletion of 46-110 amino acid of the N-terminal region of SHP2 was sufficient to induce resistance to cell death upon cisplatin treatment and decrease P73 and p21^{cip} levels needed to induce apoptosis; *PTPN11*/SHP2 via its SH2 domain is constitutively and physically associated with c-Abl SH3 domain and regulates DNA damage-induced apoptosis via P73 stabilization (L. Yuan et al. 2005). c-Abl associates with 14-3-3 and remain sequestered in the cytoplasm, however, is translocated to the nucleus by JNK phosphorylation of 14-3-3 and P73 phosphorylation together with acetylation by EP300 to form P73-EP300-Pin1 complex. This prevents ubiquitin-mediated proteasomal degradation by ITCH, an E3 ubiquitin ligase, and transcription of P73 responsive genes, including pro-apoptotic and P21 mediated cell cycle arrest genes (Costanzo et al. 2014b). Besides c-Abl further mediates YAP phosphorylation at Tyr 357 upon DNA damage and this allows YAP to change its binding partner from Runt related transcription factor 1 (RUNX1) to P73 via its WW domain preventing the binding of ITCH and recruitment of P73 to pro-apoptotic gene promoters like BAX (Levy et al. 2008).

PTPN11/SHP2 also activates PLK1 to phosphorylate BUBR1 and activate Aurora B kinase to localize it on the kinetochore for proper formation of kinetochore to spindle mitotic tubules and

formation of metaphase plate as observed in HeLa cells (Liu, Zheng, and Qu 2012). A summary of our literature survey is presented in the flowchart below:

To assess any putative tumor suppressor role of loss of *PTPN11*/SHP2 in breast cancer as observed in our breast cancer clinical metadata analysis (in Chapter 3), we knocked down *PTPN11*/SHP2 in MCF10A, a non-transformed breast epithelial cell line. We sought to verify the possible tumor suppressor role of *PTPN11*/SHP2 by studying the effects of its loss in the transformation of, otherwise, normal breast epithelial cells. Using normal cells was important to examine the molecular context of its tumor suppressor role unperturbed by hormonal receptor signaling. We report *PTPN11*/SHP2 knockdown in MCF10A promotes hallmarks of cancer like an increase in migration and a decrease in chemosensitivity to epirubicin without affecting proliferation. The knockdown of *PTPN11*/SHP2 functions as a negative regulator of tumorigenesis at least in MCF10A, as observed in our study.

4.2: Methods

Cell culture

MCF10A cells were harvested in DMEM media from thermofisher scientific (#10566-016) with 100units/ml of Penstrep (#15140122). Growth media was supplemented with 5% horse serum (#26050088, GIBCO) and 20ng/ml of EGF (#E9644, Sigma), 0.5ug/ml of hydrocortisone (#H0888-5G, Sigma), 100ng/ml of cholera toxin (#C8052-1MG, Sigma) and 10ug/ml of insulin (# I1882-100MG, Sigma).

Mycoplasma Testing

Cells were routinely checked for mycoplasma contamination and cleared (if any) using LookOutO mycoplasma elimination Kit (#MP0030).

Cell Passaging

Monolayer MCF10A cells from passage 23 to passage 32 were used for all experiments. Media from monolayer cells was aspirated, rinsed with DPBS (3D8537-500ML), and trypsinised for 10-15 mins using 0.05% Trypsin EDTA (# 25300054, Thermofisher Scientific). The cells were incubated at 37 degrees C, 5% CO₂; dissociated cells were resuspended in DMEM with 10% horse serum and centrifuged at 2000 RPM, 6mins. Cells were seeded in a 1:4 ratio and they reach confluency of 80-90% by 3-4 days. The cells were cultured for 6 passages at any time and discarded.

siRNA transfection

Cells were seeded at 0.16 million per 6 well and scaled down according to the plate used. 24 hours post-seeding, cells were rinsed in DPBS and grown in serum-free media (growth media without horse serum and pen strep) 24 hours before transfection. Cells were transfected using lipofectamine RNAi max (#13778150, Thermofisher Scientific) and two independent Accell *PTPN11* siRNA, Targeted Region: 3'UTR (A-003947-18-0005, denoted as #18 and A-003947-19-0010, denoted as #19) at 500nM and 1uM concentrations, respectively, in serum-free media. The equimolar concentration of *LACZ* siRNA was used as a control for each. 24 hours post-transfection, the transfection media was aspirated out and cells were replenished with growth

media. Following 48 hours of transfection, growth media was aspirated out and cells were rinsed in serum-free media 1 hour before the second shot of transfection. Cells were again transfected and 48 hours post-second transfection all experiments were carried out. All experiments were carried out using both the siRNA, data for si18 is shown. Knockdown efficiency was 60-70% estimated at the protein level. The sequences of *LACZ* siRNA used is below:

LACZ: 5'-CGUACGCGGAAUACUUCGA-3'

3'-GCAUGCGCCUUAUGAAGCU-5'

(dTdT overhang)

RNA isolation and qPCR

Total RNA was isolated using TRIzol reagent (Sigma) and estimated using nanodrop. 500ng RNA was converted to cDNA with superscript III first-strand synthesis for RT-PCR (#1191-7010). Synthesized RNA was diluted in DNase free water and mixed with SYBR fast qPCR master mix from Kappa biosystems (KK4601) and processed using the BioRad CFX96 real-time qPCR system. All mRNA quantification of the target gene was optimized to housekeeping control, GAPDH, or an average of housekeeping controls (ACTB, RPLPO, or PUM1) and quantitated using the $\Delta\Delta CT$ method or average RNU. Primer sequences used are as follows:

| Gene | Sequence |
|---------|----------------------------|
| PTPN11 | F: CGGAAAGTGTGAAGTCTCCAG |
| | R: GCGGGAGGAACATGACATC |
| YAPI | F: ACGTTCATCTGGGACAGCAT |
| | R: GTTGGGAGATGGCAAAGACA |
| GAPDH | F: AATGAAGGGGTCATTGATGG |
| | R: AAGGTGAAGGTCGGAGTCAA |
| B-Actin | F: TTCCTGGGCATGGAGTC |
| | R: CAGGTCTTTGCGGATGTC |
| RPLPO | F: GGCTGTGGTGTGATGGGCAAGAA |
| | R: TTCCCCGGATATGAGGCAGCAGT |
| PUM1 | F: CCGGAGATTGCTGGACATATAA |
| | R: TGGCACGCTCCAGTTTC |

Cell lysis and western blotting

Cells were washed thrice in ice-cold DPBS, followed by the addition of cell lysis buffer (RIPA: 20mM Tris (pH=8), 420mM NaCl, 10% glycerol, 0.5% NP40, 0.1mM EDTA, water to add up the volume) and incubated in ice for 40 mins to allow complete lysis. The lysates were collected using a cell scraper and centrifuged at 13,000 RPM, 15mins. The supernatant was collected in labelled tubes and mixed with 1X lamelli buffer and heated at 95 degrees, 5mins. SDS PAGE was run at 70V in stacking gel and at 100V in resolving gel and then transferred to the PVDF membrane for 90mins at 90V and 4-degree C. The transferred membrane was blocked in 5% BSA or 5% Milk for 1 hour followed by the addition of primary antibody in 2% BSA or 2% Milk and then incubated overnight at 4-degree C. The following day, the primary antibody was removed and the membrane was washed thrice with (0.1%) TBST. A secondary antibody conjugated to HRP was added in 1:10,000 dilutions in 2% BSA or 2% milk and incubated for 1hour at room temperature. Secondary antibody incubation was followed by 0.1% TBST wash and developed using an ECL kit (Merck). Densitometry analysis was used for quantitation of protein expression levels using Image J. The expression levels were normalized to housekeeping genes, GAPDH, or β Actin.

Cell Number

PTPN11/SHP2 knocked down cells were trypsinised and centrifuged at 2000 RPM, 6mins. The cell pellets were dissolved in 1ml growth media and counted using a haemocytometer.

Cell Size

Immunofluorescence images were captured at 63x oil objective in Leica SP8 confocal microscope. ROI of each cell was calculated for the area using Image J. A total of 100 cells across 3 biological replicates were analysed.

Cell morphology

Immunofluorescence images were captured at 63x oil objective in Leica SP8 confocal microscope. At least 60% of the cell population were imaged and analysed for change in morphology.

MTT assay

10ul of 5mg/ml of MTT (#M5655-100MG) was added to 100ul of cells in growth media. Growth media alone is used as a blank. We incubated the cells after MTT addition for 3.5 hours at 37-degree C and aspirated the media with MTT. Post 3.5 hours, 100ul of DMSO (#D2438-50ml, Sigma) added, kept in a shaker for 5mins and measured absorbance at 570nm and 650nm.

Immunofluorescence microscopy

Growth media was aspirated and cells were rinsed in DPBS. Cells were fixed with 4% PFA (Sigma) for 10mins. PFA was aspirated and cells were rinsed again in PBS, for 10mins each, repeated thrice. Cells were permeabilised and blocked with 2% FBS in 0.03% PBST (30ul Triton X (Sigma) in 10ml DPBS) for 30mins. Following permeabilization, the primary antibody was diluted in DPBS before adding and incubated overnight at 4-degree C. Following primary incubation, cells were rinsed in 0.05% PBST (5ul Tween20 (Sigma) in 10ml DPBS) for 10mins each, repeated thrice. Cells were mounted in prolong gold Antifade DAPI or incubated in DAPI (1:1000) for 1 min and washed with DPBS before mounting (#P36931 and D9542).

Wound healing assay

Monolayer cells were treated with 10ug/ml of mitomycin C (Sigma M4287) for 2 hours before initial scratch. Cells were wounded using a 10ul sterile micropipette tip. Scratch was rinsed with DPBS, following which growth media were added to wells. Cells were acclimatized at 37-degree C for 10mins before recording a 0-hour wound distance. 3 areas per sample were recorded. 24 hours post initial wound, images of the same area recorded at 0-hour were re-measured with EVOS FL Auto. Wound distance was calculated using ImageJ, grid lines 1, 3, 5, and 7 were used for all analyses, and an average of a total of 12 data points per sample was used for all analyses. For analysis, 24-hour wound distance was subtracted from 0-hour wound distance and normalized to 0-hour wound distance (as the initial scratch was not the same across samples) and multiplied by 100 (percentage wound closure). We performed a double normalization by subtracting the percentage wound closure of every sample from its control siLACZ. Data points were plotted in GraphPad prism.

Transwell invasion assay

K913-24 transwell assay kit was used to compare the invasion capacity of *PTPN11*/SHP2 knockdown cells. For invasion assay, we serum-starved *PTPN11*/SHP2 knockdown cells at 72 hours of knockdown (18-24 hours before invasion assay). Post which cells were then trypsinised and seeded at a concentration of 0.5-1 million cells/collagen-coated wells. The standard curve was plotted using MCF10A and growth media was used as blank. 24 hours later, cells that migrated to the lower chamber were processed using the manufacturer's protocol.

Flow cytometry and cell cycle analysis

Cells were trypsinised and centrifuged at 2000 RPM, 6mins. The cell pellet was washed with DPBS by gentle vortexing and centrifuged at 2000 RPM, 6mins. The step was repeated twice. Following DPBS wash, cells were fixed in ice-cold 70% ethanol for 30 mins. Post fixation samples were centrifuged at 2000 RPM, 6mins. The cell pellet was washed with DPBS and centrifuged again at 2000 RPM, 6mins. Cells were treated with RNase (DS0003) (to remove any RNA contamination) for 5mins in ice. Following incubation, 5ul of Propidium Iodide (PI) in a 1million cells/sample was added 5mins before the acquisition. The samples were acquired in BD FACS Calibur and BD FACS Celesta. An analysis was performed in BD software.

Apoptosis

Following epirubicin treatment for 24 hours, cells in media supernatant were collected in labelled tubes. Attached cells were trypsinised and collected in the respective tube and centrifuged at 2000 RPM, 6mins, 4-degree C. Cells were washed with ice-cold DPBS and centrifuged at 2000 RPM, 6mins. The cell pellet was dissolved in ice-cold 90ul 1X Annexin binding buffer and added 5ul of Annexin V and 5ul Propidium iodide. The samples were incubated for 5mins with 0.25mM CaCl₂ in dark and imaged and analysed in Operetta, Perkin Elmer.

Antibodies

The following antibodies were used:

| Antibody Name | Catalog number | Working Conc. | Dilution in |
|--|------------------------------|-------------------|----------------|
| SHP-2 (D50F2) Rabbit mAb | 3397 | 1:1000 | 2% BSA |
| Phospho-SHP-2 (Tyr542) Antibody rabbit mAb | 3351 | 1:1000 | 2% BSA |
| Anti-YAP1 antibody [EP1674Y] | ab52771 | 1:1000 | 2% Milk |
| Anti-YAP1 (phospho Y357) antibody | ab62751 | 1:2000 | 2% BSA |
| cABL | 2862 | 1:1000 | 2% BSA |
| Anti-p73 antibody [EP436Y] | ab40658 | 1:5000 | 2% Milk |
| Anti-Bax antibody [E63] | ab32503 | 1:10,000 | 2% Milk |
| Anti-gamma H2A.X (phospho S139) antibody [9F3] | ab26350 | 1:10,000 | 2% Milk |
| Anti-Ki67 antibody [EPR3610] | ab92742 | 1:100 | DPBS |
| Anti-MMP9 antibody [EP1254] | ab76003 | 1:10,000 | 2% BSA |
| Purified Mouse Anti-E-Cadherin Clone 36/E-Cadherin (RUO) | 610181 | 1:1000 | 2% BSA |
| Purified Mouse Anti-N-Cadherin Clone 32/N-Cadherin (RUO) | 610920 | 1:1000 | 2% BSA |
| Purified Mouse Anti-Fibronectin Clone 10/Fibronectin (RUO) | 610077 | 1:1000 | 2% BSA |
| B catenin | #9562S | 1:1000/1:500 | 2% BSA or DPBS |
| Propidium Iodide - 1.0 mg/mL Solution in Water | P3566 | 1ul/million cells | DPBS |
| Annexin V, Alexa Fluor® 488 Conjugate | A13201 | 5ul/million cells | DPBS |
| Vimentin | V9 clone, Santacruz | 1:1000 | 2% BSA |
| B actin | Santacruz | 1:1000 | 2% BSA |
| Lamin B1 | 16048 | 1:1000 | 2% Milk |
| B Tubulin | Rg000140 | 1:2000 | 2% Milk |
| GAPDH | RG000110 | 1:2500 | 2% Milk |
| Secondary Anti-Rabbit Alexa 568 | Invitrogen, Molecular probes | 1:10,000 | DPBS |
| Secondary Anti-Rabbit Alexa 488 | Invitrogen, Molecular probes | 1:10,000 | DPBS |
| Secondary Anti-Rabbit HRP | Invitrogen, Molecular probes | 1:10,000 | 2% Milk/BSA |
| Secondary Anti-Mouse HRP | Invitrogen, Molecular probes | 1:10,000 | 2% Milk/BSA |
| Secondary Anti-Rat HRP | Invitrogen, Molecular probes | 1:10,000 | 2% Milk/BSA |

Statistical Analysis

Column statistics (GraphPad Prism) was used for statistical analysis, $p < 0.05$ was considered significant. Unpaired T-Test was used for survival assay. P values are flagged as * ($p < 0.05$), ** ($p < 0.01$) and *** ($p < 0.001$).

4.3: Results

4.3.1: siRNA mediated silencing of *PTPN11*/SHP2 in MCF10A

We successfully knocked down *PTPN11*/SHP2 in the monolayer culture of MCF10A with two independent siRNAs. We achieved 50-70% depletion of SHP2 protein (A, B) and 80-90% depletion of *PTPN11* mRNA expression (C) in si18/19 transfected MCF10A cells.

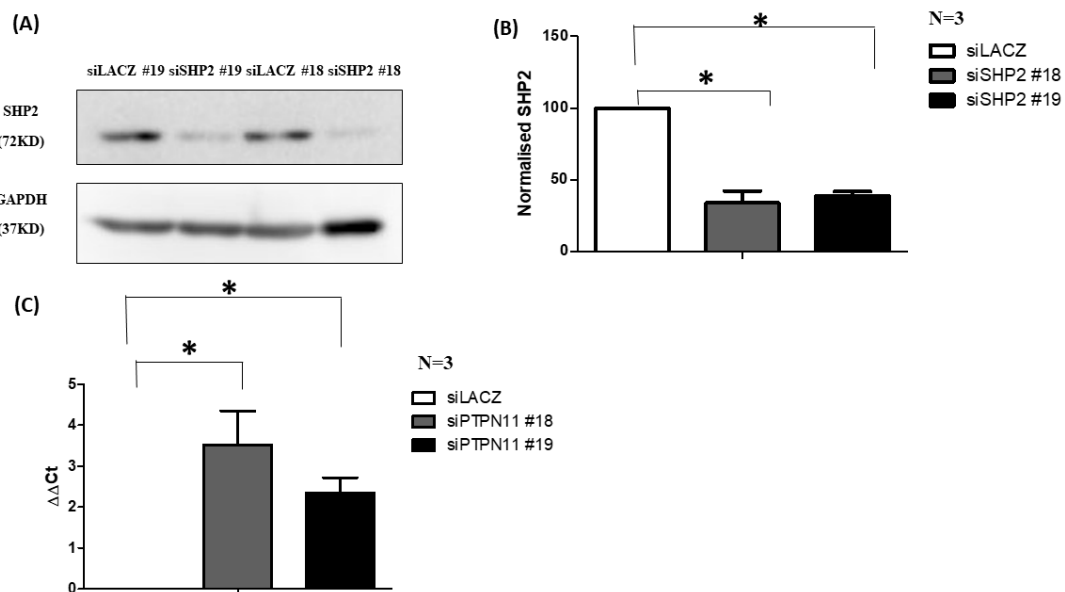

Figure 4.3.1: (A) Western blot (WB) showing expression of *PTPN11*/SHP2 in MCF10A transfected with individual *PTPN11*/SHP2 siRNA #18 and #19, GAPDH was used as a loading control. (B) Densitometric analysis of the protein expression level shows a 60% knockdown. (C) qPCR of *PTPN11* mRNA in MCF10A transfected with individual siRNA #18 and #19 shows 2.5-3.5 CT difference from LACZ control, data normalized to the average of housekeeping gene controls, β -Actin, Pum1, and RPLPO.

4.3.2: Effect of PTPN11/SHP2 knockdown on the transformation of MCF10A

4.3.2A: Effect of PTPN11/SHP2 knockdown on proliferation and survival

We report from our clinical data analysis of TCGA RPPA in chapter 3, low expression of Phospho-SHP2Y542 correlates to significantly larger tumor size in breast adenocarcinoma. To understand the role of *PTPN11/SHP2* expression alone in proliferation and survival of breast epithelial cells we looked at a widely used proliferation marker, Ki67, upon *PTPN11/SHP2* knockdown (A, B). We do not observe any significant change in the proliferation index of MCF10A cells upon *PTPN11/SHP2* knockdown. We also examined cell survival upon *PTPN11/SHP2* knockdown by MTT assay for 4 days. We measured cell survival at 72 hours (Day 0), 96 hours (Day 1), 120 hours (Day 2), 144 hours (Day 3) of the first transfection (C, D).

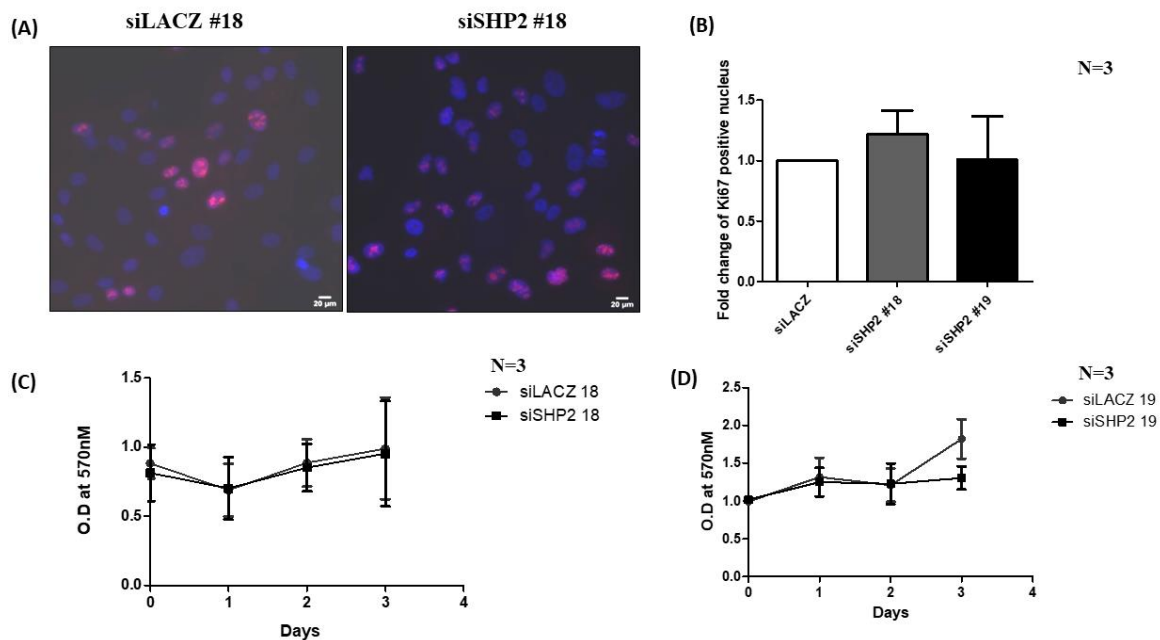

Figure 4.3.2A: (A) Immunofluorescence (IF) images showing proliferation index Ki67, a bonafide proliferation marker in control, and *PTPN11/SHP2* knockdown cells. Ki67 was probed with a secondary antibody, Alexa 568 (Red), and DAPI stained the nucleus (Blue). We imaged at 20x lens and analysed in Perkin Elmer's Operetta system. We counted the ki67 positive nucleus and normalized to the total number of nucleus per field (n=100 cells). The cells were also imaged at

40x using a DM8 Epifluorescence microscope for the image provided. The image for si18 is shown, however, data was reconfirmed with si19. The scale bar in A is 20uM. (B) shows the quantitation of Ki67 change between SHP2 knockdown cells and control. (C) and (D) shows there was no change observed in cell survival in all 4 days of our assays using siRNA 18 and 19 respectively. Cell survival O.D values were normalized to day 0 and plotted in graph pad prism. For each biological replicate, we had 4 technical replicates.

4.3.2B: Effect of *PTPN11*/SHP2 knockdown on cell cycle

PTPN11/SHP2 has been reported to regulate cell cycle checkpoints including the G1-S transition (Tsang et al. 2012), G2-M phase (L. Yuan et al. 2005), and transition from metaphase to anaphase (Liu, Zheng, and Qu 2012) upon DNA damage. We reconfirmed the effects of *PTPN11*/SHP2 knockdown on the cell cycle pattern in MCF10A and observed no significant change either with si18 or si19. We also assessed the effects of *PTPN11*/SHP2 knockdown upon DNA damage on cell cycle pattern post epirubicin (a DNA damaging drug) treatment for 24 hours. We did not observe changes in cell cycle patterns upon epirubicin treatment in *PTPN11*/SHP2 knockdown MCF10A (Supplementary figure 1A, 1B, 1C).

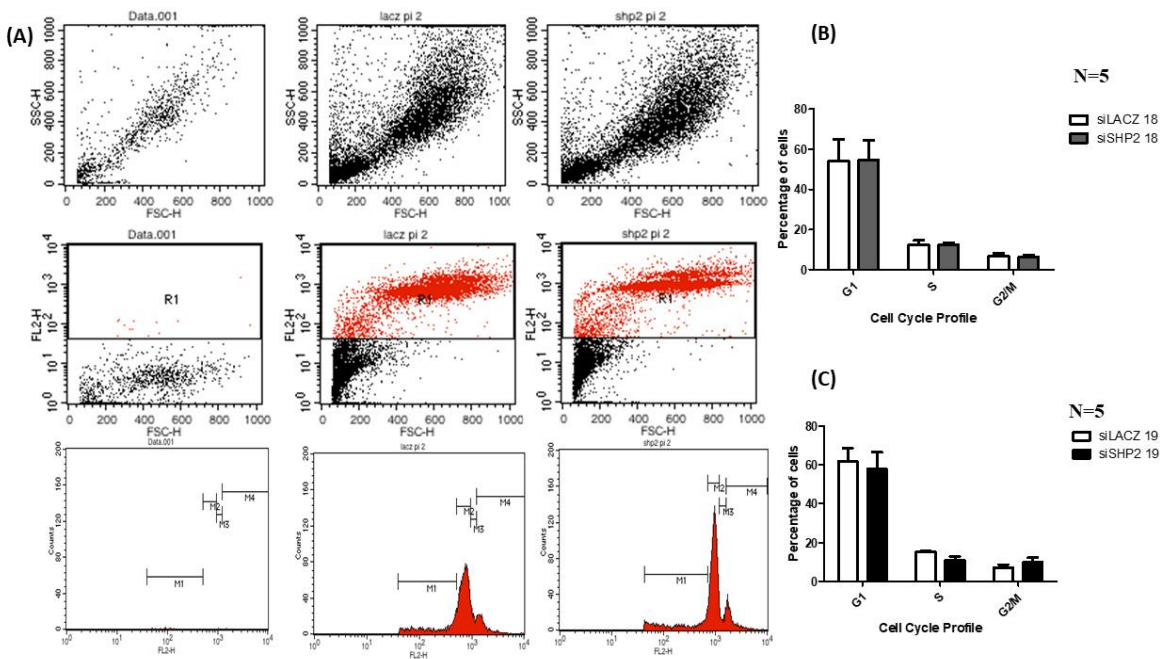

Figure 4.3.2B: (A) Flow analysis showing cell cycle pattern of control and *PTPN11*/SHP2 knockdown cells, with scatter plots showing selected population for analysis and histogram

showing cell cycle phases denoted with gate, M. Flow analysis for si18 is shown, however, data was reconfirmed with si19. M1 which is the sub G1 population was not quantitated in our analysis. For the cell cycle pattern, 10,000 cells were recorded by Flow cytometry after PI staining. (B) and (C) shows quantitation of cell count in G1 (M2), S (M3), and G2/M (M4) phases of the cell cycle, no significant change observed in *PTPN11*/SHP2 knockdown cells with si18 and si19 respectively.

4.3.2C: Effect of *PTPN11*/SHP2 knockdown on cell number and cell size

To re-confirm our observation on the effect of *PTPN11*/SHP2 knockdown on proliferation, we examined changes in cell size (A) and cell number (B) of MCF10A cells. We did not observe any significant change in any growth parameters of MCF10A upon *PTPN11*/SHP2 knockdown in our system.

Figure 4.3.2C: (A) Cell size was measured by immunostaining of β -Catenin, an adheren junction protein to mark the borders of the cell. The cell size was quantitated by measuring the ROI of cells (area in μm^2). At least 100 cells across 5 fields and 3 biological replicates were recorded for quantitation. There was no change observed in cell size. (B) Quantitation of cell number (Hemocytometer count) did not show any difference in *PTPN11*/SHP2 knockdown cells.

4.3.2D: Effect of *PTPN11*/SHP2 knockdown on migration and invasion

We assessed the effect of *PTPN11*/SHP2 knockdown on other hallmarks of cancer like migration and invasion. We observed *PTPN11*/SHP2 knockdown cells migrate 25% more in 24 hours of initial scratch (A, B). Interestingly, we also observed a change in cell morphology. A confluent

monolayer of MCF10A cells appeared cobblestone-like whereas *PTPN11*/SHP2 knockdown cells acquired mesenchymal or elongated morphology (C). However, we do not observe any change in invasion capacity (measured by fluorescence (D)) of *PTPN11*/SHP2 knockdown cells in both serum-free and media supplemented with 5% horse serum using both si18 (E) and si19 (F).

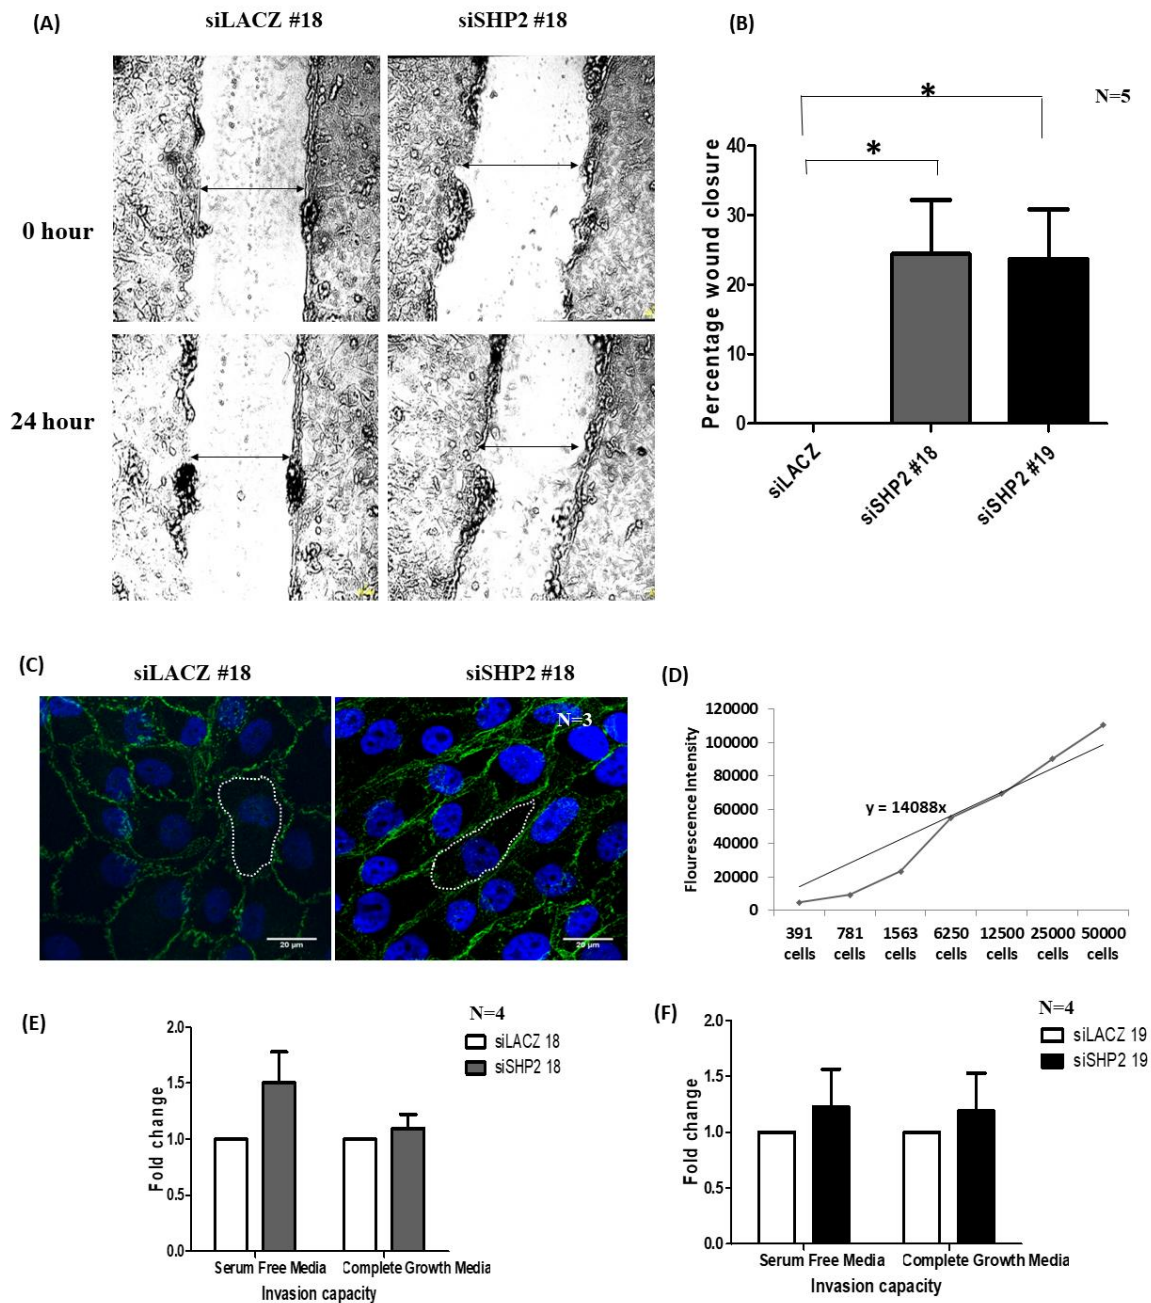

Figure 4.3.2D: (A) Scratch assay showing the initial wound at 0 hours and gap closure post 24 hours of scratch (shown by arrow). (B) Quantitation of the percentage wound closure normalized

to control. (C) shows IF images of MCF10A cells stained with β -catenin, adheren junction protein stained with Alexa 488 (Green), and DAPI (Blue) staining the nucleus. The white inlet is used to show the change in morphology from cobblestone to mesenchymal shape. (D) A standard curve showing fluorescence intensity versus cell number for transwell invasion assay Biovison kit. (E) and (F) shows *PTPN11*/SHP2 knockdown cells do not show any significant changes in the invasion capacity through a matrigel coated transwell when knockdown with si18 and si19 respectively.

4.3.2E: Effect of *PTPN11*/SHP2 knockdown on epithelial to mesenchymal transition status

PTPN11/SHP2 targets Vimentin and inhibits migration (Yang et al. 2019). We examined if *PTPN11*/SHP2 knockdown increases migration and transformation of MCF10A cells to mesenchymal morphology by epithelial to mesenchymal transition (EMT) and activation of mesenchymal markers. We assessed whether *PTPN11*/SHP2 knockdown targets expression of its bonafide target Vimentin, a mesenchymal marker. We also examined other bonafide EMT markers like E-cadherin, N-cadherin, Fibronectin, and Matrix Metalloprotease (MMP) 9. We observed approximately 2-fold increases in MMP9 (B), fibronectin (C), and Vimentin (D) expression but it was not significant across siRNAs. We did not observe any change in E-cadherin levels (E) and could not detect N-cadherin at the desired molecular size (data not shown). Our data suggest *PTPN11*/SHP2 knockdown increases migration due to an increase in other EMT markers as the sub-optimal increases in expression of Vimentin, fibronectin, and MMP9 are not sufficient to drive complete transformation or induce invasion. We also checked for β -catenin levels in the nucleus and cytoplasm by IF, but could not detect any changes in β -catenin levels upon *PTPN11*/SHP2 knockdown (data not shown).

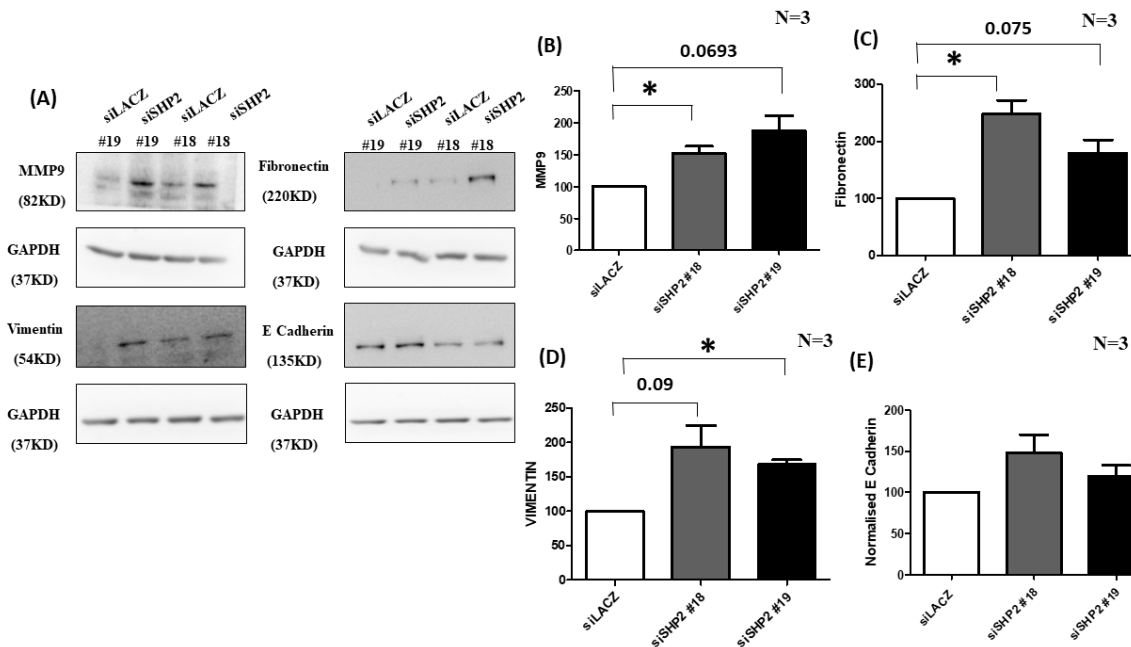

Figure 4.3.2E: (A) shows western blot for total MMP9, Vimentin, Fibronectin, and E cadherin. GAPDH was used as a loading control. Quantitation of representative blots shows a near significant increase in expression of (B) MMP9, (C) fibronectin, and (D) Vimentin but no (E) change in epithelial marker like E-cadherin. There were no detectable N-Cadherin levels in both control and *PTPN11*/SHP2 knockdown cells (data not shown).

4.3.2F: Effect of *PTPN11*/SHP2 knockdown on sensitivity to chemotherapeutic drugs

As discussed earlier, *PTPN11*/SHP2 plays a major role in cell cycle and DNA damage (Tsang et al. 2012). We, therefore, assessed the effect of *PTPN11*/SHP2 knockdown on chemosensitivity. We treated cells with chemotherapeutic drugs like carboplatin, epirubicin, and paclitaxel (Konecny et al., 2001). Carboplatin inhibits replication and transcription and induces DNA breaks and cell death (Jiang et al. 2015). Epirubicin intercalates between DNA and inhibits DNA and RNA synthesis, it induces double-stranded DNA breaks and cell death (Konecny et al. 2001). Paclitaxel interferes with mitotic spindle assembly and chromosomal segregation and cell death (Jordan and Wilson 2004). We determined the Inhibitory Concentration (IC) 50 of these cell cycle and DNA synthesis interfering drugs. We used concentration in the range of 100uM to 1000uM for carboplatin, 100nM-100uM for epirubicin, and 10nM-100uM for paclitaxel to optimize the

IC50. We observed MCF10A had high IC50 for carboplatin while paclitaxel was not effective in bringing about 50% cell death (Supplementary figure 2A, 2C). Epirubicin with IC50 of 1uM was the drug of choice for further treatments (Supplementary figure 2B). The effectivity of epirubicin (EPR) to introduce double-stranded DNA breaks in cells was measured by phosphorylation of Serine 139 gamma H2AX upregulation in MCF10A cells upon epirubicin treatment for 24hours (Supplementary figure 2D, 2E). We observed *PTPN11*/SHP2 knockdown cells show better survival upon epirubicin treatment for 24 hours at 1uM concentration of the drug (A, B). We examined if *PTPN11*/SHP2 knockdown cells show changes in apoptosis upon EPR treatment. *PTPN11*/SHP2 knocked down cells do not affect ploidy or cell cycle pattern upon EPR treatment (Supplementary figure 1). We observed *PTPN11*/SHP2 knocked cells had a 2-fold decrease in early apoptotic cells (Annexin positive), late apoptotic cells (Annexin+ PI double positive) and dead cells (PI positive) (C, D). We hypothesis from our data, *PTPN11*/SHP2 knockdown interferes with apoptotic marker synthesis and provides survival advantage to MCF10A cells. Our literature survey to understand the role *PTPN11*/SHP2 in DNA damage suggested a putative role of BAX in providing survival advantage to cells upon DNA damage in *PTPN11*/SHP2 knockdown cells.

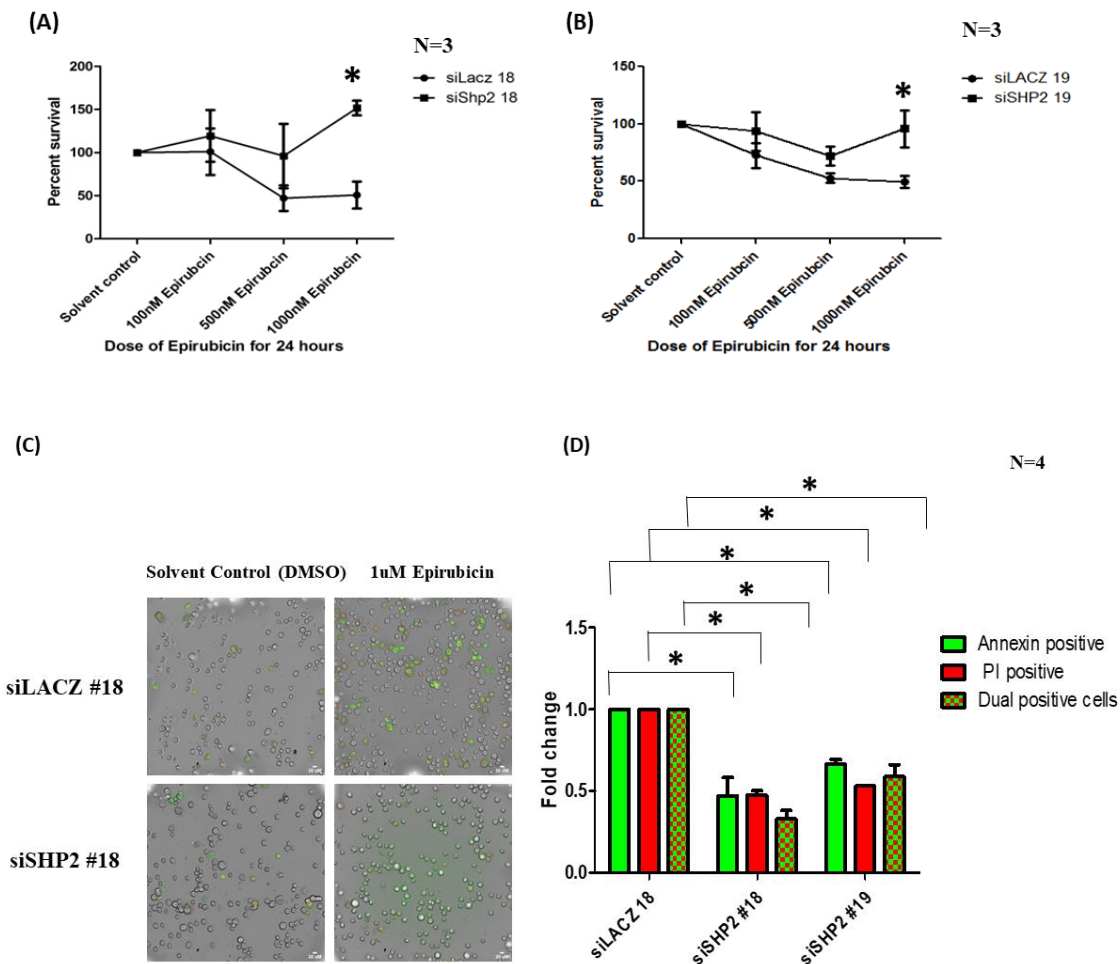

Figure 4.3.2F: (A) and (B) shows the results of MTT assay showing the dose-response curve upon EPR treatment in *PTPN11*/SHP2 knockdown and control cells. We observed an increased survival advantage in *PTPN11*/SHP2 knockdown cells at 1uM concentration of EPR with si18 and si19 respectively. (C) IF images showing the effect on apoptosis upon EPR treatment in *PTPN11*/SHP2 knockdown. The Scale bar is 20uM. (D) Quantitation shows a 2-fold decrease in Annexin positive, Annexin+ PI double-positive, and dead PI-positive cells. IF staining was performed with Annexin V (Alexa 488, green) and propidium iodide (red), imaged with 20X lens, and analyzed in Perkin Elmer operetta.

4.3.2G: Effect of *PTPN11*/SHP2 knockdown on BAX expression upon epirubicin treatment

We have previously shown the role of *PTPN11* upon DNA damage. One of the several aspects of *PTPN11* upon DNA damage is to induce c-Abl and mediate P73 stabilization and induction of apoptosis via BAX as hypothesized from our literature survey (4.1.2). We experimentally confirmed the effect of *PTPN11*/SHP2 knockdown on BAX expression (A). We also checked the expression of Phospho YAP1-Y357, c-Abl, and P73 (data not shown) but we did not observe any significant change in the expression of BAX and other predicted molecules (Data not shown) of our hypothesis (B). We report *PTPN11*/SHP2 employs other apoptotic pathways such that its knockdown decreases apoptosis and increases cellular survival.

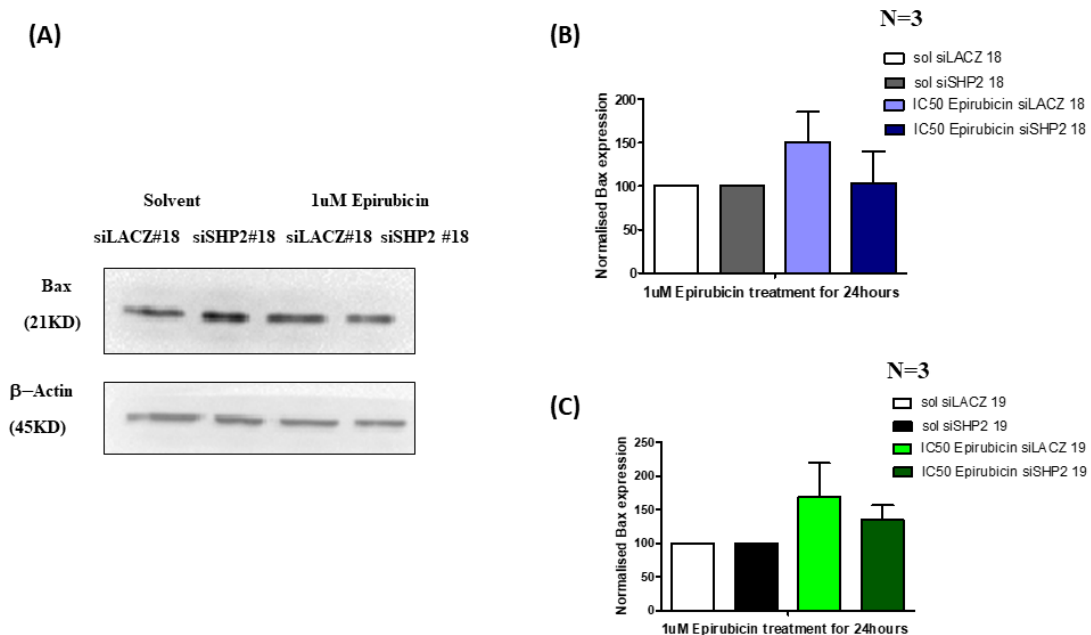

Figure 4.3.2G: (A) Western blot analysis showing the expression of BAX in 24-hour epirubicin (1uM) treated cells. β actin was used as a loading control. (B) and (C) shows densitometry analysis shows *PTPN11*/SHP2 knockdown does not affect BAX expression levels when knocked down with either si18 and si19.

4.4: Discussion

Constitutively active *PTPN11/SHP2* is reported to function in positive feedback signaling of EGFR and other growth factor receptors (Agazie and Hayman 2003; Neel, Gu, and Pao 2003). Loss of *PTPN11/SHP2* in HER2 overexpressing MCF10A inhibits breast cancer progression by interfering with tumor-initiating cell maintenance (Aceto et al. 2012). Alternatively, it is reported to inhibit migration and podosome formation by regulating the polymerization of Vimentin (Y. R. Pan et al. 2013; Yang et al. 2019). The overexpression or loss of *PTPN11/SHP2* in the non-tumorigenic background like MCF10A has not been reported earlier. Our approach was to understand the intrinsic tumorigenic role of *PTPN11/SHP2* in the non-transformed background using a loss of function genetics. The results of our study show knockdown of *PTPN11/SHP2* at least in MCF10A functions in priming cells to more migratory behaviour.

The role of *PTPN11/SHP2* as a putative tumor suppressor from our clinical study in chapter 3 was re-confirmed experimentally. The knockdown of *PTPN11/SHP2* in MCF10A did not affect any growth parameters but increased migration and chemoresistance. We propose, *PTPN11/SHP2* being a phosphatase, functions like a key which helps to auto-tune signaling pathways and change cellular fate. We also report *PTPN11/SHP2* suppression increases vimentin, fibronectin, and MMP9 mesenchymal markers which is not significant enough to increase migration in *PTPN11/SHP2* knocked down breast epithelial cells. The turnover of these mesenchymal markers is tightly controlled in a non-transformed cell line like MCF10A and *PTPN11/SHP2* knockdown alone is not sufficient for complete transformation and invasiveness and other players seem to be involved.

In the context of DNA damage, *PTPN11/SHP2* is reported to regulate death due to DNA damage and cell cycle by regulating Cdc25c, c-Abl, and BAX (Tsang et al. 2012; L. Yuan, Yu, and Qu 2003). Our findings suggest a loss of *PTPN11/SHP2* provides a survival advantage to the cells by decreasing apoptosis upon DNA damage. However, it is not via BAX as predicted from literature mining studies. BAX being a global apoptotic molecule might be under the control of several signaling pathways and *PTPN11/SHP2* loss does not alter BAX levels. *PTPN11/SHP2* could be interacting with other apoptotic markers that need to be further investigated.

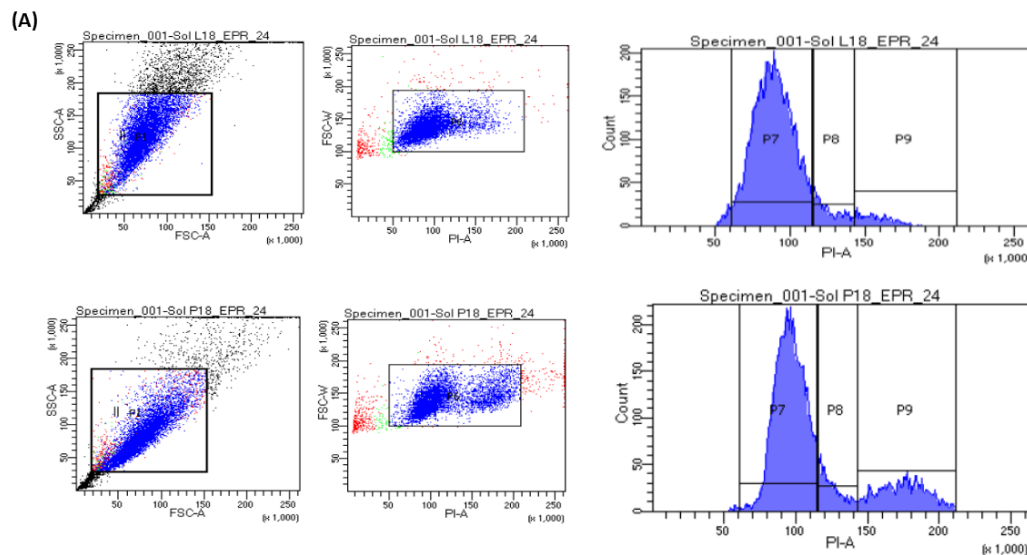

Whether or not *PTPN11/SHP2* is a tumor suppressor is a question that needs detailed context-specific analysis. Inhibition of *PTPN11/SHP2* is reported to induce a transition to the Basal

subtype from the luminal subtype of breast cancer (H. Zhao and Agazie 2015). The scope of the study allows investigation of the loss of *PTPN11*/SHP2 in 2D monolayer MCF10A cells. MCF10A in monolayer culture expresses both luminal and basal markers (Qu et al. 2015). This study limits the analysis of whether *PTPN11*/SHP2 functions as a tumor suppressor is limited to any subgroup of breast cancer. Since breast cancer is a heterogeneous disease, each requiring a specific therapeutic course, elucidation of *PTPN11*/SHP2 behaviour in specific subtype and individual context becomes more relevant for cancer therapy and diagnosis.

In Summary, our study shows loss of *PTPN11*/SHP2 promotes migratory behaviour and provides survival advantage upon anthracycline treatment in breast epithelial cells, which are evident hallmarks of epithelial cancer. Cell culture validation together with clinical observations in METABRIC 2012 and TCGA RPPA data 2015 (Chapter 3), *PTPN11*/SHP2 is a negative regulator in breast tumorigenesis. Whether like EGFR, prominent oncogene such as YAP1, provides a context to tumorigenic behaviour of a phosphatase like *PTPN11*/SHP2 in breast cancer needs investigation and is discussed in Chapter 5.

4.4: Supplementary data

Figure 1:

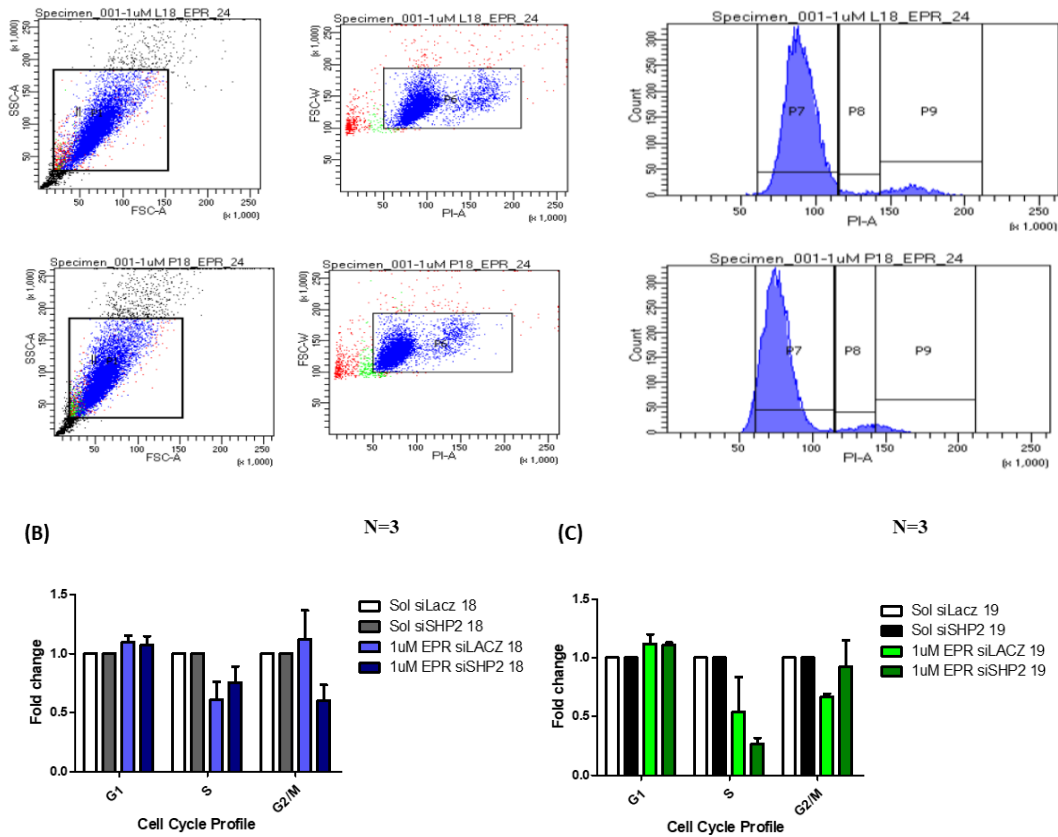

Figure 1: (A) Flow analysis showing cell cycle pattern upon epirubicin treatment for 24 hours, represented are the scatter plots showing selected population for analysis and histogram showing cell cycle phases denoted with gate, P. Flow analysis for si18 is shown, however, data was reconfirmed with si19. For the cell cycle pattern, 10,000 cells were recorded by Flow cytometry after PI staining. (B) Quantitation of cell count in G1 (P7), S (P8), and G2/M (P9) phase show no significant change in *PTPN11*/SHP2 knockdown cells with si18 and si19 respectively.

Figure 2:

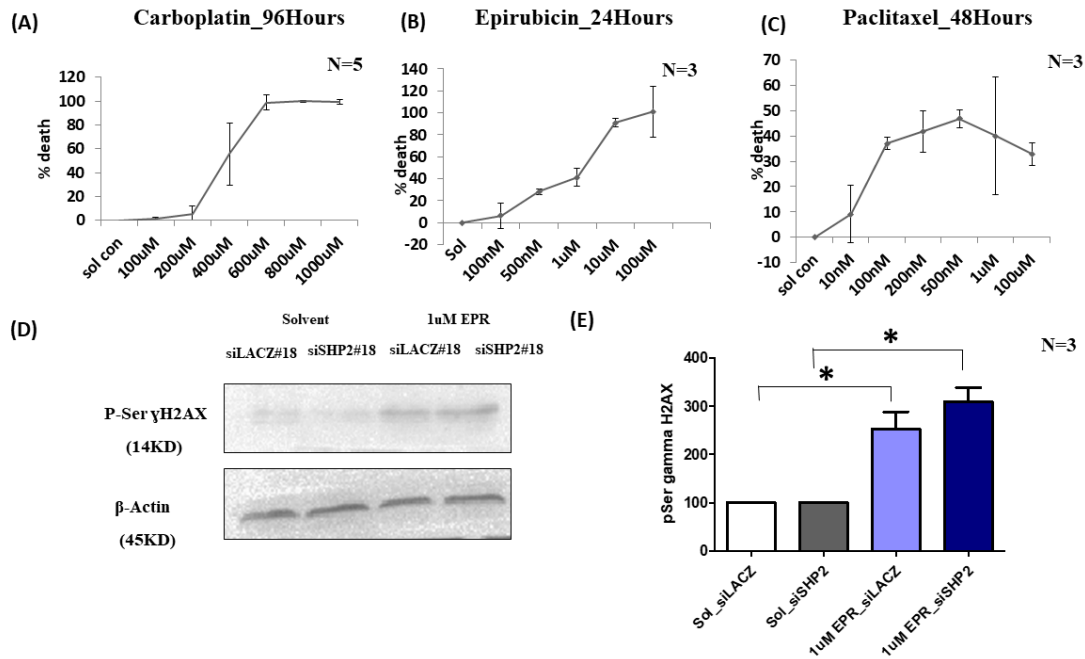

Figure 2: (A) MTT assay shows the dose-response curve of 3 chemotherapeutic drugs in MCF10A, IC50 for carboplatin was 400uM. (B) Epirubicin showed an IC50 of 1uM at 24 hours (C) while for Paclitaxel the IC50 could not be determined as cell death plateaued at 45-50 percent. (D) Effectivity of epirubicin (EPR), an anthracycline which induces double-stranded DNA breaks in cells, western blot showing phosphorylation of Serine 139 gamma H2AX upregulation in MCF10A cells upon epirubicin treatment for 24hours, (E) shows quantitation by densitometry analysis and a 3-fold increase in Serine 139 gamma H2AX phosphorylation.

Chapter 5: Function of *PTPN11*/*SHP2* in tumorigenesis in the background of YAP1 overexpression

5.1: Introduction

The hippo pathway effector YAP1 is a prominent oncogene in breast cancer (D. Pan 2010). *PTPN11*/*SHP2* association with YAP1 is recently reported in HCC, AGS gastric epithelial cells, and non-small cell lung cancer (NSCLC) (Chen et al., 2019; Kim et al., 2018; Tsutsumi et al., 2013). At low cell density of gastric epithelial cells, *PTPN11*/*SHP2* is reported to physically interact with YAP1/TAZ and is translocated to the nucleus to dephosphorylate parafibromin and activate the wnt signaling pathway (Tsutsumi et al. 2013). Moreover, the nuclear association of YAP1 and *PTPN11*/*SHP2* correlates to poor prognosis of NSCLC patients possibly due to activation of wnt signaling and higher c-myc and cyclin D1 expression (Chen et al. 2019). Furthermore, in SK-Hep1 cells, *PTPN11*/*SHP2* -YAP1 nuclear association was pro-tumorigenic, while in HCC patient samples, higher nuclear YAP1 correlated to low cytoplasmic *PTPN11*/*SHP2* and poor prognosis (Kim et al., 2018). In breast cancer, both YAP1 and *PTPN11*/*SHP2* are pro-tumorigenic (Overholtzer et al., 2006; Aceto et al., 2012). Studies on gastric epithelial cells, NSCLC, and HCC patients suggest, YAP1 may influence *PTPN11*/*SHP2* localization and hence its tumorigenic function. To assess the influence on *PTPN11*/*SHP2* localization and its tumorigenic function in the presence of a prominent oncogene like YAP1 in breast cancer, we investigated the effect of over-expression of YAP1 in MCF10A breast epithelial cells with and without *PTPN11*/*SHP2* activity (the latter was achieved by its knock-down).

5.2: Methods

Stable over-expression of YAP1 in MCF10A

MCF10A cells were cultured to 60% confluency and transduced with a cocktail solution of 2ml, 48hours retroviral particles, pQCXIH, and 8 ug/ml Polybrene (Sigma). pQCXIH carrying wild type YAP1 (YAP1-WT) and constitutively active YAP1 (YAP1-5SA) inserts were used as genetic backgrounds to check the role of *PTPN11*/*SHP2* in YAP1 driven tumors and pQCXIH was used as empty vector control. Post 4 hours of transduction, a top-up of growth media of 12 ml was

added to plates. The following day, a growth medium change was given to cells. 48hours of viral transduction, selection with 100ug/ml of Hygromycin (Sigma) was given and cells were selected until 50% cells died in control MCF10A plates. Following selection, plates were rinsed in DPBS and added fresh growth media to allow them to grow till 80-90% confluency. As cells grew completely, stocks were prepared and used for all experiments. Retroviral vector, pQCXIH cloned with YAP1, and YAP-5SA was a generous donation from Dr. Madhura Kulkarni, Center for Translational Cancer Research, Prashanti Cancer Care Mission, and IISER Pune.

Details of all other methods used in this chapter are described in Chapter 4. All experiments were repeated with #18 and #19 siRNA, data of #18 is shown here. Column statistics (GraphPad Prism) was used for statistical analysis, $p < 0.05$ was considered significant.

5.3: Results

5.3.1: Overexpression of YAP1 in MCF10A

We successfully transduced MCF10A cells to stably overexpress YAP1-WT and YAP1-5SA using the pQCXIH vector (A). In YAP1-WT overexpressing MCF10A, once the cells reach confluency, the hippo pathway is turned on and YAP1- WT is phosphorylated by upstream LATS kinase at Ser 127 and relocated to the cytoplasm by 14-3-3 β (Meng, Moroishi, and Guan 2016). In the case of overexpression of YAP1-5SA, in which all five serine (S) residues including S127 were mutated to alanine (A) that prevents phosphorylation of YAP1 at S127 and hence results in constitutive translocation of YAP1 into the nucleus even at high confluency and continued transcription of YAP1 driven genes (Pavel et al. 2018). These two genetic systems are expected to confirm our observation from the *Drosophila* screen viz Csw (the ortholog of *PTPN11*/SHP2) functioning as a tumor suppressor in the context of over-expressed Yorkie. Figure A gives the vector map of pQCXIH used for stably overexpressing YAP1-WT and YAP1-5SA. We observed a fold change of 1.5x and a 3x increase in YAP1 expression in YAP1-WT and YAP1-5SA transduced MCF10A cells, respectively as compared to MCF10A cells with the empty vector control (B and C).

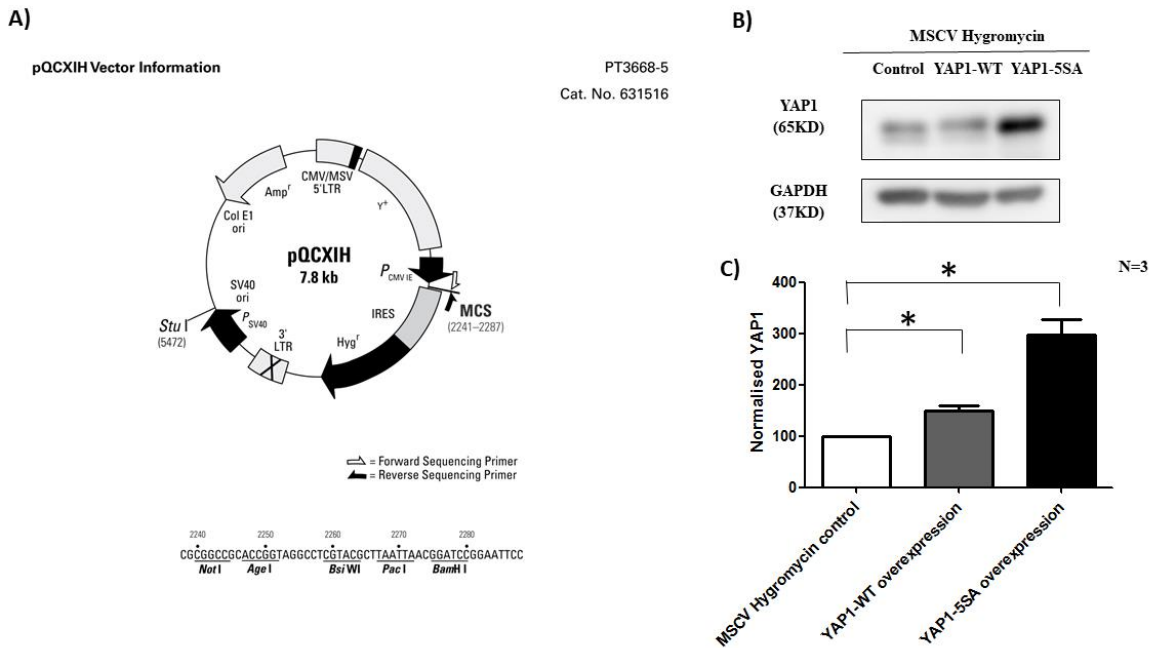

Figure 5.3.1: (A) YAP1 was overexpressed under a hygromycin selection vector of 7.8kb in MCF10A by transduction of 48 hours. Vector map shown in, image reproduced from clontech. (B) Western blots showing expression of YAP1. MSCV vector control, YAP1-WT cloned MSCV and YAP1-5SA cloned MSCV. GAPDH was used as a loading control. (C) Densitometry analysis of blot shows a 1.5-fold increase in YAP1-WT protein expression and a 3-fold increase in constitutive YAP1-5SA expression.

5.3.2: Effect of YAP1 overexpression on *PTPN11*/SHP2 expression and activity

Phospho-SHP2Y542 is a marker for *PTPN11*/SHP2 activity. Overexpression of YAP1, both WT and constitutive 5SA, decreases *PTPN11*/SHP2 phosphorylation at Y542 with no change in *PTPN11*/SHP2 total protein levels (A, B) or RNA levels (C). This may reflect decreased *PTPN11*/SHP2 activity with increased YAP1 expression.

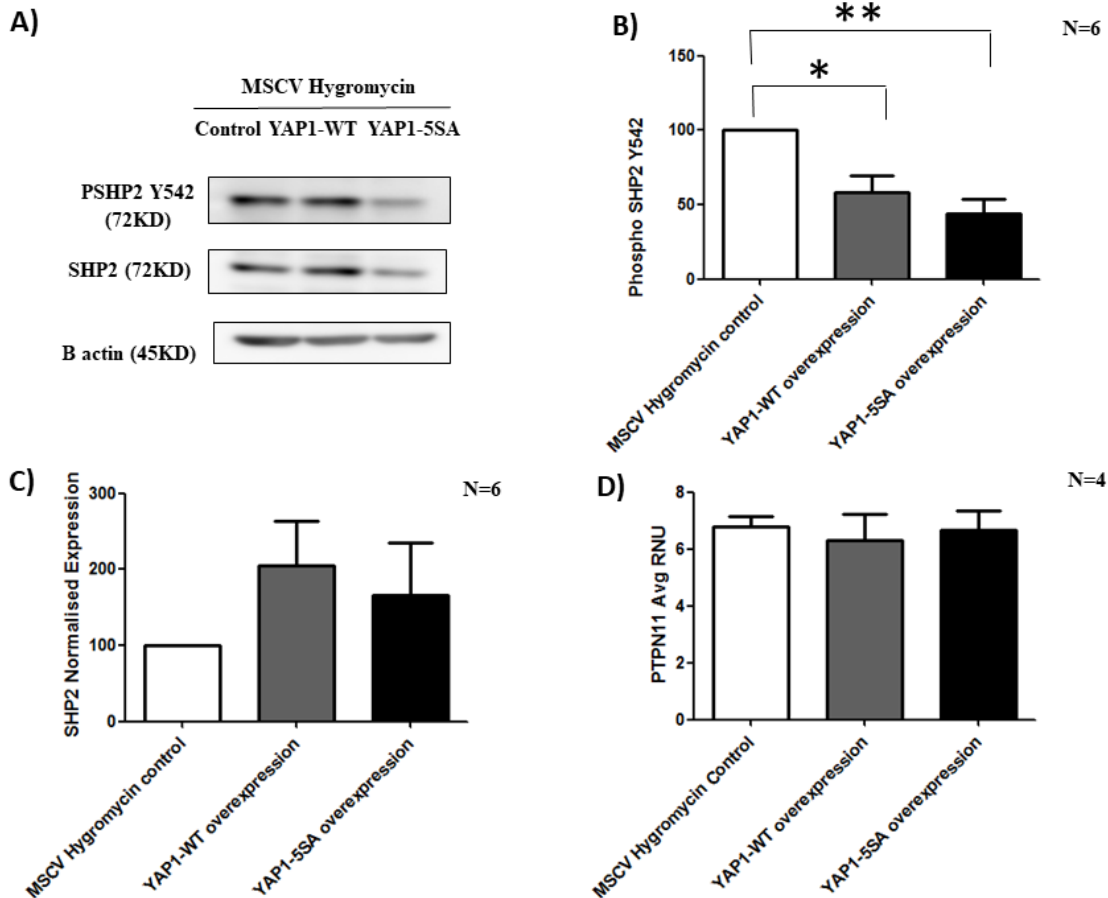

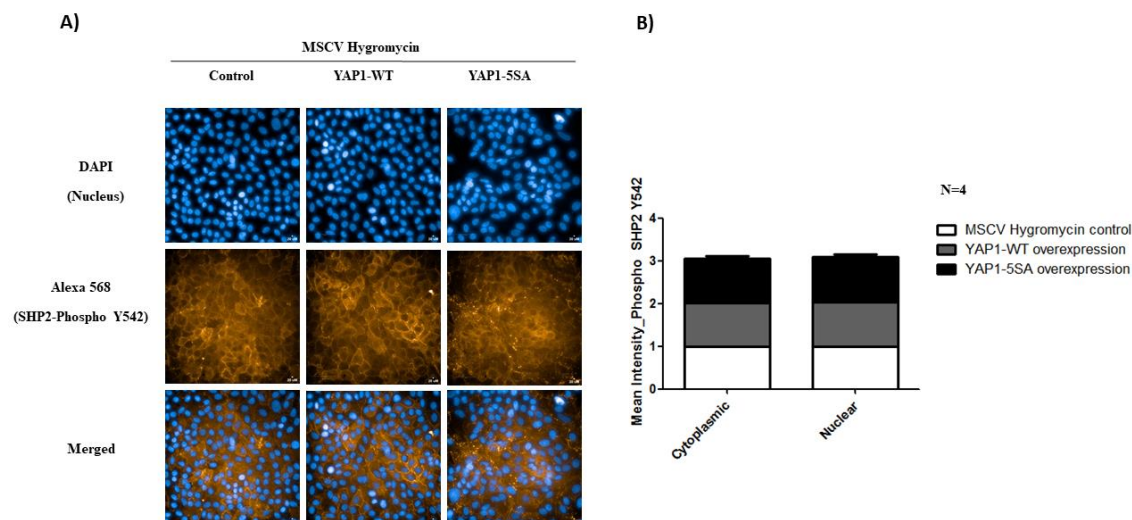

Figure 5.3.2: (A) Overexpression of YAP1, both wild type and constitutively active, results in the decrease in the levels of phospho-SHP2 without affecting total *PTPN11*/SHP2 expression. Western blot for total *PTPN11*/SHP2, phospho-SHP2, and B actin. (B) Densitometric analysis of the Western blot of phospho-SHP2. (C) Densitometric analysis of the Western blot of total *PTPN11*/SHP2. (D) Transcript levels of *PTPN11* by qRT-PCR normalized to GAPDH.

5.3.3: Effect of YAP1 overexpression on Phospho-SHP2Y542 subcellular localization

As reported in the literature, YAP1 regulates *PTPN11*/SHP2 localization however our preliminary data suggested a plausible association between YAP1 and *PTPN11*/SHP2 activity (Figure 5.3.2). We investigated changes in the subcellular localization of Phospho-SHP2Y542 and not SHP2 total protein as we did not observe any change from our densitometric analysis (Figure 5.3.2). We selected the confluent monolayer of YAP1-overexpressing MCF10A cells for all localization studies. YAP1 localization itself is influenced by cellular confluency and mechanical cues (Meng,

Moroishi, and Guan 2016). To understand the role of YAP1 expression alone on *PTPN11*/SHP2 activity, devoid of any external contributions from mechanical cues and YAP1 localization itself. Although overexpression of YAP1 leads to decreased Phospho-SHP2Y542 levels, we did not observe any considerable change in the subcellular localization of Phospho-SHP2Y542. However, in MCF10A cells overexpressing YAP1-5SA, Phospho-SHP2Y542 shows more punctate distribution on the membrane unlike the uniform distribution observed in the case of empty vector control or MCF10A cells overexpressing YAP1-WT (A, B). We speculate this punctate appearance of Phospho SHP2 could result from a change in membrane localization of receptors. However, the observation needs further experimental validation with high-resolution microscopy. We re-confirmed the localization of SHP2 and Phospho-SHP2Y542 by fractionation assay (REAP protocol, (Suzuki et al. 2010)). We did not see any considerable change in the levels of *PTPN11*/SHP2 or Phospho-SHP2Y542 in the nuclei or cytoplasm of cells over-expressing YAP1-WT or YAP1-5SA (C, D).

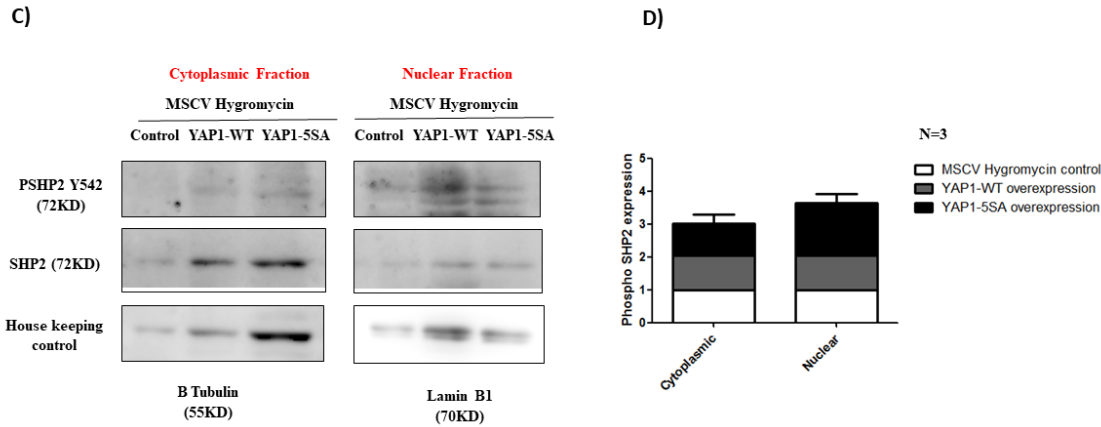

Figure 5.3.3: (A) Overexpression of YAP1-WT or YAP1-5SA does not affect the subcellular localization of Phospho-SHP2Y542 as observed either by immunofluorescence imaging and (B) Quantitation in operetta, 40X air, Scale bar in A is 20uM. (C) Subcellular localization was also re-confirmed by cellular fractionation assays followed by Western blot analysis. β -tubulin was used as a control for cytoplasmic fraction, while Lamin B1 was used as a control for the nucleus for Western blot analysis. (D) Densitometry analysis of the above Western blot shows no significant change in the expression of *PTPN11*/SHP2 or Phospho-SHP2Y542.

5.3.4: Effect of knockdown of *PTPN11*/SHP2 in the background of overexpressed YAP1 on the morphology of MCF10A cells

As described in chapter 4, knockdown of *PTPN11*/SHP2 induces changes in the morphology of MCF10A: from cobblestone to mesenchymal shape. We investigated changes in morphology upon overexpression of YAP1-WT and YAP1-5SA in the presence or the absence of *PTPN11*/SHP2. We did not observe any morphological changes in MCF10A cells overexpressing YAP1-WT along or in the background of the knockdown of *PTPN11*/SHP2. However, overexpression of YAP1-5SA alone causes mesenchymal morphology of MCF10A cells and the degree of change was higher compared to the change caused by the knockdown of *PTPN11*/SHP2. The combined effect, i.e. caused by the over-expression of YAP1-5SA and the knockdown of *PTPN11*/SHP2 was similar to YAP1-5SA alone.

Figure 5.3.4: (A) Morphological changes in MCF10A cells caused by the knockdown of *PTPN11*/SHP2 in the normal background or the background of the over-expression of YAP1-WT or YAP1-5SA. Scale bar 20uM. Images recorded in Evos FL Auto. YAP1-WT appears to suppress the effect of knockdown of *PTPN11*/SHP2. The severity of the morphological change is higher in cells over-expressing YAP1-5SA, which appears to be saturated as knockdown of *PTPN11*/SHP2 in this background did not alter the degree of morphological changes.

5.3.5: Effect of knock-down of *PTPN11*/SHP2 in the background of overexpressed YAP1 on the proliferation of MCF10A cells

YAP1 has been reported to increase cell proliferation (Varelas 2014). Although we did not observe any effect of the knockdown of *PTPN11*/SHP2 on cell proliferation, we examined the phenotypic effects of over-expression of YAP1 in the background with and without *PTPN11*/SHP2. While we did observe increased cell proliferation due to the over-expression of YAP-WT, we did not see such changes when we over-expressed constitutively active YAP1-5SA. There was no impact of *PTPN11*/SHP2 knockdown on the phenotypic effect of the over-expressing YAP1-WT or YAP1-5SA.

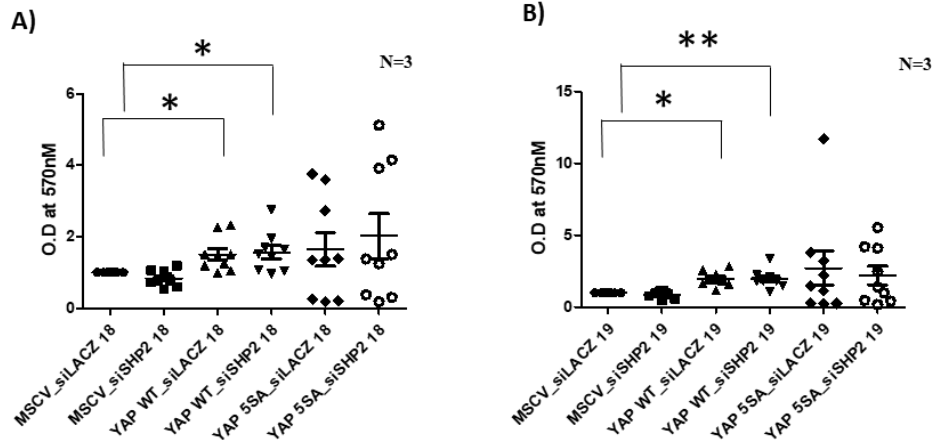

Figure 5.3.5: (A) MTT assay showing the effect of over-expression of YAP and/or knockdown of *PTPN11*/SHP2 with siSHP18 and (B) with siSHP19 on cell proliferation, while over-expression of YAP1-WT had a marginal increase in the cell proliferation by 2-fold, there was no effect in any other combinations.

5.3.6: Effect of overexpression YAP1 and knockdown of *PTPN11*/SHP2 on cell migration

Wound healing scratch assay was performed to investigate if YAP1 and *PTPN11*/SHP2 have any combined effect on cell migration. As described in chapter 4, we observed accelerated cell migration in the background of the knockdown of *PTPN11*/SHP2. Over-expression of YAP1-WT or YAP1-5SA does not significantly affect migration post 24 hours of initial scratch in our system. Over-expression of YAP1-WT appears to suppress the accelerated rate of migration caused by the knockdown of *PTPN11*/SHP2 by 5%-15%. Over-expression of YAP1-5SA, however, did not affect the increased migration caused by the knockdown of *PTPN11*/SHP2.

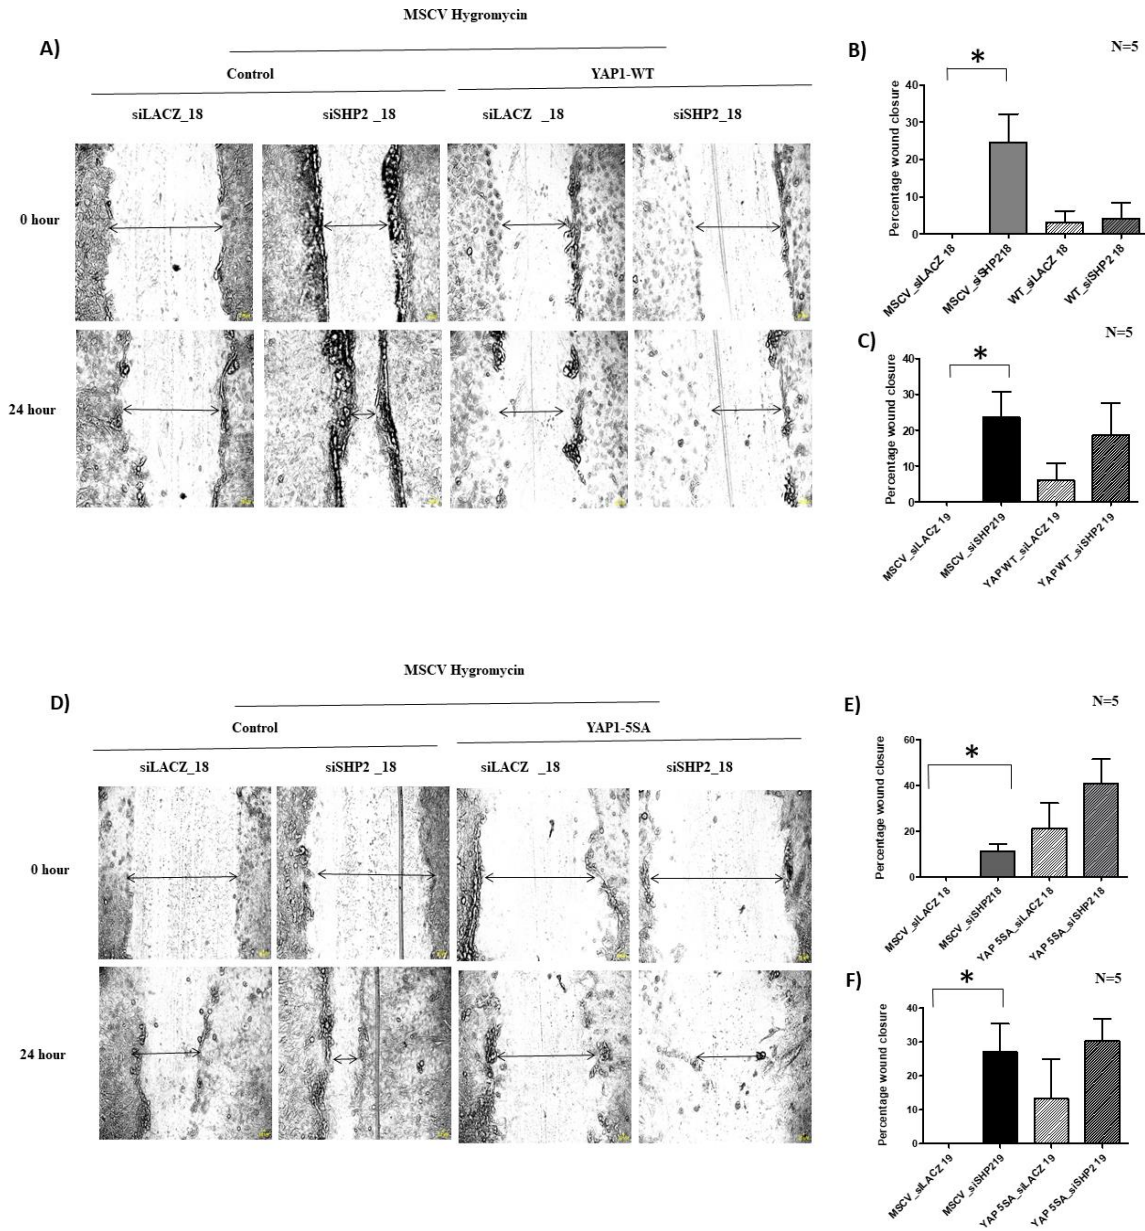

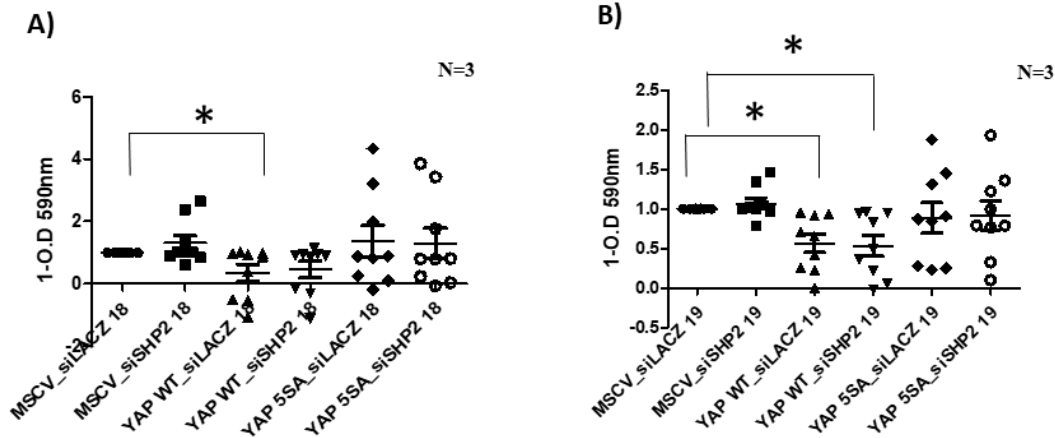

Figure 5.3.6: Wound healing scratch assay to measure the migration capacity of MCF10A cells. (A) and (C) show the level of gap-filling after 24h of the scratch, (B), and (D) show the quantitation of these experiments. The migration capacity of cells in which *PTPN11*/SHP2 is knocked down is increased by nearly 25% as compared to empty vector control, which is also reported in the previous chapter. There was no effect of the over-expression of YAP1-WT and YAP1-5SA. While over-expression of YAP1-WT appears to suppress the effect of the knockdown of *PTPN11*/SHP2 to some extent, over-expression of YAP1-5SA did not affect the increased migration caused by the knockdown of *PTPN11*/SHP2.

5.3.7: Effect of overexpression YAP1 and knockdown of *PTPN11*/SHP2 on cell death

YAP1 is reported to decrease cell death in cells (Varelas 2014). In our experiments, overexpression of YAP1-WT resulted in decreased cell death. However, over-expression of YAP1-5SA, which did not affect cell proliferation did not have any impact on cell death either. Neither of them showed any change in their phenotypic effect when over-expressed in the background with knockdown of *PTPN11*/SHP2 (A, B).

We reported in our study in chapter 4, *PTPN11*/SHP2 knockdown provides a survival advantage to cells, which are treated with cytotoxic chemical epirubicin at 1uM concentration. Overexpression of YAP1-WT and YAP1-5SA did not affect the survival of cells upon treatment with 1uM epirubicin. Overexpression of YAP1-WT without *PTPN11*/SHP2 shows increased survival upon 1uM epirubicin treatment for 24hours. However, overexpression of YAP1-5SA with and without *PTPN11*/SHP2 nullifies the effect of *PTPN11*/SHP2 knockdown on chemosensitivity.

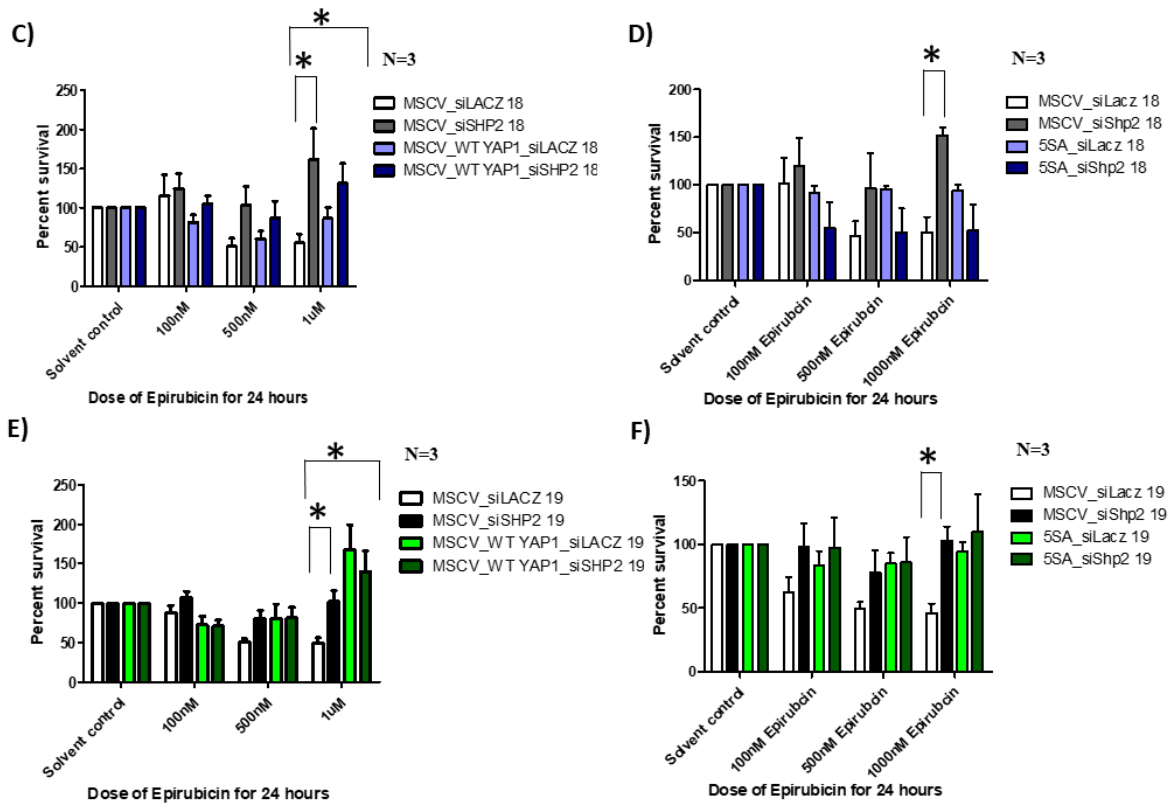

Figure 5.3.7: (A) and (B) shows MTT assay (1-O. D value) showing cell death in YAP1 overexpressing MCF10A with and without *PTPN11*/SHP2 knockdown using si18 and si19 respectively. (C) shows the increased survival of *PTPN11*/SHP2 knockdown (si18) cells alone and together in the background of YAP1-WT overexpressing MCF10A at 1uM conc. of epirubicin. (D) shows the increased survival of *PTPN11*/SHP2 knockdown (si18) cells alone and the effect is lost in the background of YAP1-5SA overexpressing MCF10A at 1uM conc. of epirubicin. (E) shows increased survival of *PTPN11*/SHP2 knockdown (si19) cells and together in the background of YAP1-WT overexpressing MCF10A at 1uM conc. of epirubicin. (F) shows an increase in survival of *PTPN11*/SHP2 knockdown (si19) cells however in the background of YAP1-5SA overexpressing MCF10A the chemoresistance is lost at 1uM conc. for 24 hours. MTT assay results were normalized to solvent control.

5.4: Discussion

The oncogenic role of YAP1 has been reported in several studies, wherein copy number amplification of YAP1 in MCF10A is shown to promote anchorage-independent growth, EMT,

growth factor independent proliferation, and decreased apoptosis (Overholtzer et al. 2006). Overexpression of constitutively active YAP1-5SA is also reported to promote proliferation even in highly confluent cultures by inducing autophagy in 2D and 3D cultures of MCF10A (Pavel et al. 2018; B. Zhao et al. 2009). In recent studies, the oncogenic role of YAP1 in breast cancer stands controversial as new data suggests, loss of heterozygosity of YAP1 amplicon, or its knockdown in MDA-MB231 and MCF7 leads to increased migration and tumor growth (M. Yuan et al. 2008). Furthermore, YAP1 expression negatively correlates to relapse-free survival in the luminal subgroup of breast cancer patients (Cao, Sun, and Yao 2017; Lehn et al. 2014). In a sample of 137 Indian breast cancer patients, the YAP1 promoter was reported to be methylated in 67.15% of cases with decreased YAP1 mRNA expression suggestive of its putative tumor suppressor role (Real et al. 2018).

From experimental evidence in our work, overexpression of either YAP1-WT or constitutively active YAP1-5SA resulted only in a marginal increase in cell proliferation, migration, and cell survival (in the context of DNA damage). As they were not significant, we infer that overexpression of YAP1 alone is not sufficient to drive tumorigenesis.

We also observed that overexpression of YAP1 decreases the levels of phospho-SHP2 indicating possible interaction and regulation of *PTPN11*/SHP2 by the hippo pathway effector. However, this interaction was not evident in any of the phenotypic assays suggesting more complex interactions during tumorigenesis. This may reflect a possible dual role (oncogenic vs tumor suppression) of both YAP1 and *PTPN11*/SHP2 in breast cancer progression. Therefore, a detailed investigation of the phenotypic effect of YAP- *PTPN11*/SHP2 interaction is required to unravel complex pathways associated with breast carcinogenesis.

Overexpression in MCF10A of YAP1-5SA alone or the context of knockdown of LATS is shown to induce expression of Connective Tissue Growth Factor (CTGF) and Cysteine-rich angiogenic inducer 61 (CYR61) and transforms MCF10A to mesenchymal morphology, with no effect in proliferation (J. Zhang, Smolen, and Haber 2008). Overexpression of YAP1-5SA in MCF10A activates LATS to induce Neurofibromatosis 2 (NF2) expression in MCF10A cells, preventing stress fiber formation and cell migration (Moroishi et al. 2015). These observations further support the complexity of the YAP1 function as an oncogene. Thus, studying the role of *PTPN11*/SHP2 in tumorigenesis in YAP1 overexpression background is challenging and an alternative approach

to answering the same could be employed. It would be interesting to check the effects of knockdown of LATS kinase in the presence and absence of *PTPN11*/SHP2 (caused by its knockdown) and record changes in migration and proliferation.

Summary and Future Perspective of study

Organ growth is a tightly coordinated process, any dysregulation either due to loss of function of negative growth regulators or overactivation of growth promoters often leads to cancer. Typically, solid tumors involve at least two driver gene mutations, one in an oncogene and the other in a tumor suppressor gene or both in an oncogene that alters at least twelve different signaling pathways (Vogelstein et al. 2013). Our laboratory identified a large number of tumor suppressor genes co-operating with oncogenes like Yki and EGFR to drive tumorigenesis in an RNAi mediated screen of the *Drosophila* genome. Bioinformatic analyses reported in this study of the positives identified in the independent screens suggested hippo signaling pathway and autophagy pathways play a relevant role in both Yki and EGFR driven tumors in flies. The sensitivity of Yki as a key growth regulator is evident in our STRING analysis as we observe a larger biological hub among the positives identified in the Yki screen which is enriched in major growth regulatory pathways. Many of the negative growth regulators identified in the screen and their corresponding human orthologs (obtained using DIOPT) included hippo pathway components, P53, and many other known tumor suppressors thereby reflecting the specificity of this RNAi mediated *Drosophila* screen. Many of the positives we identified from STRING analysis also identified to be conserved and were part of the large hub in flies and humans alike with the conservation of important biological processes in these interactomes controlling the event of tumorigenesis. Among many others, we report in this study, hippo signaling, and ubiquitin-related proteolysis are most conserved in Yki driven cancer from flies to humans. *csw* is one of the few candidates we analyzed, a conserved gene in Yki driven tumors. We hypothesized it to be an essential gene, both in flies and humans, as it was a major component of the hub that mediates interactions between many MAPK related pathway genes. This was interesting as Csw orthologs are reported to participate in positive feedback signaling of the Ras-MAPK pathway (Neel, Gu, and Pao 2003). However, *csw* was negative in EGFR driven tumorigenesis in our genetic screen (Groth et al. 2019), suggestive of its redundancy in EGFR signaling. However, its role in the context of YAP1 was intriguing.

Molecularly, Csw is a non-receptor protein tyrosine phosphatase, and its human ortholog *PTPN11/SHP2* functions as an oncogene (Neel, Gu, and Pao 2003; Sondka et al. 2018). As reported from previous literature, *PTPN11/SHP2* participates in positive feedback signaling of the

EGFR pathway and drive hematologic malignancies and solid tumors including breast adenocarcinoma, prostate adenocarcinoma, lung adenocarcinoma, and colorectal cancer (Aceto et al., 2012; Prahallad et al., 2015; Richine et al., 2016; Schneeberger et al., 2015; Zhang et al., 2016). *PTPN11/SHP2*, through suppression of the JAK/STAT pathway, seems to function in inhibiting oncogenesis in hepatocellular carcinoma and esophageal squamous cell cancer (Bard-Chapeau et al. 2011; Qi et al. 2017). These observations suggest that *PTPN11/SHP2* may function either as an oncogene or a tumor suppressor, perhaps in different cellular and molecular contexts. To verify this, we carried out a retrospective investigation of publicly available clinical metadata followed by experimental validation of our hypothesis.

We report from clinical analysis using two independent breast cancer datasets, METABRIC 2012 and TCGA RPPA Level 4 2015 data, *PTPN11/SHP2* shows putative tumor suppressor function in breast cancer. *PTPN11/SHP2* copy number loss in Luminal A subtype of METABRIC cohort correlates to late-stage cancer and poor 4 years of disease-specific survival. Low expression of Phospho-*PTPN11/SHP2* Y542 in luminal A correlates to larger tumor size and greater lymph node positivity. Alternatively, *PTPN11/SHP2* functions as a putative oncogene in the luminal B subtype. A detailed pathway enrichment analysis of phosphoproteins in TCGA RPPA Level 4 2015 data as correlated to Phospho-*PTPN11/SHP2* Y542 expression levels could give us insights into the context in which it may function as a tumor suppressor in the luminal A subgroup of patients in the TCGA cohort. Since *PTPN11/SHP2* is a phosphatase, its phosphoprotein expression rather than gene expression and its implications on proteins and phospho-proteins of cancer patients are relevant in the identification of the upstream cues that is responsible for switching between its dual role in tumorigenesis. TCGA level 4 RPPA data provides the expression of a limited number of 225 protein and phosphoprotein data which could be used to understand the context of *PTPN11/SHP2* function, however, the data can be biased due to analysis on limited data availability.

Experimental validation of our clinical results by transient silencing of *PTPN11/SHP2* in non-transformed MCF10A showed that knockdown of *PTPN11/SHP2* promotes migration, changes in cell shape to mesenchymal morphology, and decreased sensitivity to chemotherapeutic drugs like epirubicin. We examined like its *Drosophila* ortholog Csw if *PTPN11/SHP2* functions as a tumor suppressor in YAP1 driven oncogenesis. However, we do not observe any additional increase in migration rate or changes in chemosensitivity upon knockdown of *PTPN11/SHP2* in

YAP1-overexpressing MCF10A. Instead, YAP1-5SA suppresses the effect of *PTPN11/SHP2* knockdown on chemoresistance. YAP1's role as an oncogene in breast cancer is itself controversial from the recently available literature (Cao, Sun, and Yao 2017; Lehn et al. 2014; Real et al. 2018; Strano and Blandino 2007; M. Yuan et al. 2008). *PTPN11/SHP2* suppression together with LATS knockdown in MCF10A could provide an unambiguous understanding of the role of the Hippo pathway in tumor suppressor function of *PTPN11/SHP2*.

Our study limits mechanistic understanding of how *PTPN11/SHP2* may function as a tumor suppressor in breast cancer cohorts of TCGA, METABRIC, and in *in-vitro* cell culture studies using MCF10A. An alternative approach to understanding *PTPN11/SHP2* tumor suppressor function in the luminal A subtype of breast cancer could be by silencing of *PTPN11/SHP2* in luminal A cell lines like T47D. As reported by others, the silencing of *PTPN11/SHP2* in T47D decreased migration rate and EMT while inhibition of *PTPN11/SHP2* in the luminal B cell line, MCF7 also is reported to decrease cell growth (Li et al. 2014; Sun et al. 2017). *PTPN11/SHP2* oncogenic and tumor suppressor role might be dependent on *in-vitro* and *in-vivo* conditions that need to be clearly defined. The dual nature of *PTPN11/SHP2* is also reported during mammary gland development, *in-vivo*, *PTPN11/SHP2* promotes STAT5 and inhibits STAT3 at different stages of mammary gland development. Selective deletion of *PTPN11/SHP2* in mouse mammary glands interferes with mammapoiesis and lactation possibly due to the disruption of epithelial architecture and lobulo-alveolar outgrowth while enhancing apoptosis and involution of mammary glands (Ke et al. 2006). This reiterates the complexity and how understanding the context specificity of *PTPN11/SHP2*'s role in tumorigenesis is necessary depending on the tissue type, the upstream cues, subtype of cancer, stage of cancer, and dose dependence of its substrate. Our study suggests *PTPN11/SHP2* functions as a negative regulator of tumorigenesis that does not seem to follow the definition of an ideal tumor suppressor rather a key that tunes signaling pathways during growth and tumorigenesis.

Author contributions

HH, CG, TE, SMC and LSS designed the screen.

CG, PV, AK, NP, AA, SN and RP carried out the genetic screen and participated in data analysis.

DA and MC carried out computational analysis.

SMC, TLS and LSS conceived of, designed and coordinated the study.

SMC and LSS analyzed the data and drafted the manuscript.

All authors gave final approval for publication and agree to be held accountable for the work performed therein.

Abstract

Genetic approaches in *Drosophila* have successfully identified many genes involved in regulation of growth control as well as genetic interactions relevant to the initiation and progression of cancer *in vivo*. Here, we report on large-scale RNAi-based screens to identify potential tumor suppressor genes that interact with known cancer-drivers: The Epidermal Growth Factor Receptor and the Hippo pathway transcriptional cofactor Yorkie. These screens were designed to identify genes whose depletion drove tissue expressing EGFR or Yki from a state of benign overgrowth into neoplastic transformation *in vivo*. We also report on an independent screen aimed to identify genes whose depletion suppressed formation of neoplastic tumors in an existing EGFR-dependent neoplasia model. Many of the positives identified here are known to be functional in growth control pathways. We also find a number of novel connections to Yki and EGFR driven tissue growth, mostly unique to one of the two. Thus, resources provided here would be useful to all researchers who study negative regulators of growth in the context of activated EGFR and/or Yki and positive regulators of growth in the context of activated EGFR.

Introduction

Studies in genetic models of tissue growth have identified networks of signalling pathways that cooperate to control growth during animal development (reviewed in [1, 2]). Normal tissue growth involves controlling the rates of cell proliferation and cell death, as well as cell size, cell shape, etc. Signalling pathways mediate hormonal and neuroendocrine regulation of growth, which depend on nutritional status. Cell interactions also contribute to coordinating growth of cells within a tissue.

Growth regulatory pathways include both positive and negative elements to allow for feedback regulation. These feedback systems confer robustness to deal with intrinsic biological noise, and with a fluctuating external environment [3]. They also provide the means for different

regulatory pathways to interact [4, 5] [6]. In the context of tumor formation, this robustness is reflected in the difficulty in generating significant mis-regulation of growth - a two-fold change in expression of many growth regulators seldom has a substantial effect on tissue size in *Drosophila* genetic models. More striking is the difficulty in transitioning from benign overgrowth to neoplasia: hyperplasia does not normally lead to neoplasia without additional genetic alterations (eg [7-9]).

Cancers typically show mis-regulation of multiple growth regulatory pathways. Mutational changes and changes in gene expression status contribute to driving cell proliferation, overcoming cell death and cellular senescence, as well as to allowing cells to evade the checkpoints that normally serve to eliminate aberrant cells. These changes alter the normal balance of cellular regulatory mechanisms, from initial cellular transformation through disease progression [10, 11]. For many tumor types, specific mutations have been identified as potent cancer drivers, with well-defined roles in disease [12, 13]. However, most human tumors carry hundreds of mutations, whose functional relevance is unknown. The spectrum of mutation varies from patient to patient, and also within different parts of the same tumor [14]. Evidence is emerging that some of these genetic variants can cooperate with known cancer drivers during cellular transformation or disease progression. The mutational landscape of an individual tumor is likely to contain conditional oncogenes or tumor suppressors that modulate important cellular regulatory networks.

Sequence-based approaches used to identify cancer genes favor those with large individual effects that stand out from the ‘background noise’ of the mutational landscape in individual cancers [10, 11]. *In vivo* experimental approaches are needed to assign function to candidate cancer genes identified by tumor genome sequencing, and to identify functionally significant contributions of genes that have not attracted notice in genomics studies due to low mutational frequency, or due to changes in activity not associated with mutation. *In vivo* functional screens using transposon mutagenesis of the mouse genome have begun to identify mutations that cooperate with known

cancer driver mutations, such as K-Ras, in specific tumor models [15-17]. Genetic approaches using *Drosophila* models of oncogene cooperation have also been used to identify genes that act together with known cancer drivers in tumor formation [8, 9, 18-20] [21, 22] [2, 23]. The simplicity of the *Drosophila* genome, coupled with the ease of large-scale genetic screens and the high degree of conservation of major signaling pathways with humans, make *Drosophila* an interesting model to identify novel cancer genes and to study the cellular and molecular mechanisms that underlie tumor formation *in vivo* (reviewed in [24-27]).

In *Drosophila*, overexpression of the Epidermal Growth Factor Receptor, EGFR, or Yorkie (Yki, the fly ortholog of the YAP oncoprotein) cause benign tissue over-growth [4, 7, 9]. Combining these with additional genetic alterations can lead to neoplastic transformation and eventually metastasis [8, 9, 21, 22] [28]. Here, we report results of large-scale screens combining UAS-RNAi transgenes with EGFR or Yki expression to identify negative regulators of these growth regulatory networks that can lead to aggressive tumor formation *in vivo*. We also performed an independent screen to identify factors that could suppress EGFR-driven neoplasia. These screens have identified an expanded genomic repertoire of potential tumor suppressors that cooperate with EGFR or Yki. Interestingly, there was limited overlap among the genes that cooperated with EGFR and those that cooperated with Yki.

Results

Overexpression of EGFR or Yki proteins in the *Drosophila* wing imaginal disc produces tissue overgrowth. Under these conditions the imaginal discs retain normal epithelial organization, but grow considerably larger than normal. However, in combination with additional genetic or environmental changes, the tissue can become neoplastic and form malignant tumors [8, 9, 22] [28]. In this context, we carried out large-scale screens using UAS-RNAi lines to identify genes which

would drive hyperplastic growth to neoplastic transformation when down-regulated. To facilitate screening for tumorous growth, we expressed UAS-GFP with UAS-EGFR or UAS-Yki to allow imaginal disc size to be scored in the intact 3rd instar larva (Figure 1A; screen design, examples and quality controls are shown in Supplemental Figure S1).

A large panel of independent UAS-RNAi lines were tested for their effects on tissue growth in the EGFR and Yki expression backgrounds (Figure 1B). Hereafter, the two screens are termed as EGFR screen and Yki screen. Of ~8800 lines tested, 74 interacted with EGFR to produce tumors (~1%), whereas 904 interacted with Yki (~10%). There was limited overlap, with only 21 RNAi lines producing tumors in both screens (Figure 1B). In a parallel screen, we started with neoplastic tumors produced by co-expression of UAS-EGFR and UAS-SOCS36E-RNAi [8] and asked whether including expression of another RNAi transgene could suppress neoplasia (Figure 1A, right panels). Hereafter, this screen is termed SOCS screen. Of ~8900 lines tested, 32 suppressed tumor formation in this assay (Figure 1B). Supplemental Table S1(A) lists the genes identified in these three screens. In previous studies, massive disc overgrowth as in Figure 1(A) was often associated with loss of apically-localized Actin and E-Cadherin: features indicative of Epithelial Mesenchymal Transition (EMT); and with formation of malignant transplantable tumors [8, 9] [22]. Apico-basal polarity and Matrix Metalloprotease 1 (MMP1) expression were assessed for a randomly selected subset of lines from the EGFR and Yki screens to assess neoplastic transformation (Figure S1 and Table S1 – second sheet).

To identify the processes and pathways responsible for the interaction with the screen drivers, we looked for over-representation of biological functions among the screen positives using gene set enrichment analysis and the KEGG, REACTOME, GO and PANTHER databases. Figure 2 presents the results of the enrichment analysis as graphical interaction maps, with similar biological processes color-coded. Edge length represents similarity between genes associated with

significantly enriched terms. Thus, similar terms are closer together and form a community of biological process. The genes in each cluster are shown in Figure 2 and listed in Supplemental Table S2 (has three sheets, once each for EGFR, SOCS and Yki screens).

Genes that potentially modulate EGFR function during growth control

For discs overexpressing EGFR, we observed enrichment of RNAi lines targeting the Hippo pathway, growth signaling, and apoptosis (Figure 2A, B). Many of the genes in the Hippo pathway act as negative regulators of tissue growth, so their depletion by RNAi is expected to promote growth. The Hippo pathway is known to interact with the EGFR pathway to regulate normal developmental growth [4, 5] [6]. The Hippo pathway hits included core elements of the pathway, *hpo*, *wts* and *mats*, which serve as negative growth regulators; the upstream pathway regulators *fat* (an atypical cadherin) and *expanded*; as well as the transcriptional corepressor *grunge*, which is linked to Hippo pathway activity (Table S2). Several of these loci also contributed to the enrichment of terms linked to apoptosis, along with *pten*, a phospholipase that serves as a negative regulator of PI3K/AKT signaling, *protein kinase A-C1*, *Src42A*, the insulin-like peptide, *ilp4*, which are also linked to growth control (Table S2).

For suppression of tumors in discs overexpressing EGFR together with SOCS36E RNAi, we observed enrichment of RNAi lines targeting signaling pathways related to growth, including elements of the AKT/PI3K pathway (Figure 2E, F, Table S2). These pathways may be required for neoplasia in this EGFR driven tumor model. As would be expected, depletion of *Egfr* limited tumor growth. Also enriched was a set of genes involved in protein synthesis (Table S2). This may reflect a need for active cellular growth machinery to support tumor growth. The significance of genes involved in RNA splicing merits further investigation.

Genes that potentially modulate Yki function during growth control

For discs overexpressing Yki, RNAi lines targeting the Hippo pathway and associated growth regulators led to tumor production (Figure 2C, D, Table S2). These include *hpo*, *sav*, *wts*, *mats*, *ft*, *ex* and *gug*. Although this has not been observed previously in *Drosophila*, it is worth noting that overexpression of YAP has been shown to lead to neoplasia in mouse liver and intestinal epithelial models [29, 30]. While most cancers appear to result from activation/inactivation of multiple genes and pathways, sufficient activation of the Hippo pathway can result in neoplasia (Yki in *Drosophila* and YAP in mouse).

The Hippo tumor suppressor pathway is regulated by cell polarity, cell contact, and mechanical forces [31-33] as well as by other growth signaling pathways. Growth signaling pathways involving the *sgg*, *pten*, *PKA-C1*, *TSCI* genes among others, were also identified. Additionally, a number of genes linked to membrane-cytoskeleton interaction and transmembrane transport were found to interact, including Arf and Rab family members. We also noted the enrichment of terms related to lipid and general metabolism. Regulation of lipid metabolism might affect the properties of cellular membranes. An intriguing subgroup contain genes related to glutamatergic signaling, including the vesicular glutamate transporter *VGlut* and the *Eaat* plasma membrane glutamate transporters. The significance of these is unclear.

The large number of Yki interactors could reflect greater sensitivity of the screen. Alternatively, it might indicate a high false positive rate. While this screen was in progress, Vissers et al. [34], reported that some of the RNAi lines from the Vienna *Drosophila* RNAi KK library have the potential to produce false positives in screens based on sensitized Hippo pathway phenotypes. This proved to be due to the presence of a second transgene landing site at 40D that was found in a subset of KK lines, in addition to the 30B landing site [34, 35]. We tested the 40D landing site

strain [34] and found that it did not cause a tumor phenotype under the conditions used for the screen. Nonetheless, we sampled the 40D status for a large subset of our Yki interactors (Table S1, 734/904) and found that 45% of them had insertions at 40D. A small survey comparing KK lines with Trip and GD lines showed that 65% of genes for which the KK line had a 40D site retested positive for interaction with Yki using an independent (non-KK) transgene (15/23). The Yki-interaction screen should therefore be viewed as a more sensitized sampling of potential interactors, compared to the EGFR-interaction screen.

STRING Interactome analyses

To view all genes identified in the three screens as one functional unit (for the fact that they were all growth regulators in one or the other contexts), we made use of STRING v10 [36] to produce protein interaction maps. STRING v10 builds interaction maps by combining experimental data (including protein interaction data) with information about functional associations from text mining. STRING v10 also uses information of co-occurrence, co-expression, gene neighborhood, gene fusion, and does sequence similarity search to predict functional interaction between proteins. An interaction pair supported by multiple lines of evidence has higher confidence score than other pairs.

Figure 3A shows the STRING interaction map for the genes identified as interactors of EGFR. As noted above, Hippo pathway (red) components were prominent among the genes identified as cooperating with EGFR to drive tumor formation. Figure 3(B) shows the interaction map for the genes identified as interactors of Yki. The larger number of hits in this screen results in a more complex interaction map, with multiple interconnected clusters. The Hippo pathway (red) was again prominent in the fly screen. We also noted clusters containing elements of the ubiquitin mediated proteolysis pathway (green) and the PI3K/TOR (blue). As noted above, the higher

sensitivity of this screen leads to the inclusion of weaker interactors, which may add to the complexity of these interaction maps. A focus on the stronger clusters and the interaction between them should guide future studies. Fig. 3(C) shows interaction map for the genes identified as interactors of EGFR in the suppressor screen (in discs overexpressing EGFR together with SOCS36E RNAi). Among fly genes, as expected, we observed suppression of the tumor phenotype when components of EGFR pathway are down regulated.

Human orthologs of the fly genes identified in the three screens

To identify human orthologs for the candidate genes, we used the DRSC Integrative Ortholog Prediction Tool, DIOPT (Version 7.1, March 2018; www.flybase.org). DIOPT scores reflect the number of independent prediction tools that identify an ortholog for a given *Drosophila* gene. Orthology relationships are usually unambiguous when found by most of the 12 independent prediction tools in DIOPT. Table S1 lists the primary human orthologs (highest weighted DIOPT score), as well as the other orthologs with a weighted DIOPT score >2 for each of the hits in the fly screen. The primary human ortholog was used for subsequent analysis. In cases where multiple human orthologs had the same score, all orthologs with highest weighted DIOPT score were used. Out of 73 EGFR positive hits, 46 genes had one or more human orthologs, in total mapping to 50 human genes. Out of 32 SOCS positive hits 30 genes had one or more human orthologs, in total mapping to 31 human genes. Out of 904 YAP positive hits 570 genes had one or more human orthologs, in total mapping to 611 human genes.

To view the human orthologs in a functional context, we performed a gene set enrichment analysis and the KEGG, REACTOME, GO, PANTHER, NCI, MsigDB, BIOCARTA databases. Figure 4 presents the results of the enrichment analyses as graphical interaction maps, with similar biological processes color-coded. Edge length represents similarity between genes associated with

significantly enriched terms. Thus, similar terms are closer together and form a community of biological processes. The genes in each cluster are shown in Figure 4 and listed in Supplemental Table S3. Because the enrichment analysis is highly sensitive to the number of orthologs for each of the fly genes, we used the minimal set consisting of only the primary human orthologs.

Hippo pathway components were enriched among the orthologs cooperating with EGFR to drive tumor formation (Fig 4A, B; Table S3). Two of these, LATS1 and STK3, also contributed to enrichment for a term linked to protein turnover. Regulation of protein turnover is an important mechanism for controlling the activity of a number of Hippo pathway components. For the screen for suppression of tumors in discs overexpressing EGFR together with SOCS36E RNAi, we observed enrichment of orthologs targeting growth signaling pathways, protein synthesis and mRNA splicing (Figure 4E, F, Table S3), similar to what was seen for the fly gene set analysis. We also observed enrichment of pathways related to protein folding and molecular chaperones, in the human gene set. For the Yki screen, the human ortholog set was enriched for terms related to general metabolism, and membrane transport, as well as growth signaling, and other signaling pathways, including genes involved in protein turnover (Fig 4C, D).

Discussion

The Hippo pathway has emerged from this study as the single most important pathway limiting tumor formation in *Drosophila*. Increasing Yki activity by depletion of upstream negative regulators promoted tumor formation in both the EGFR and Yki hyperplasia models. Yki controls tissue growth by promoting cell proliferation and by concurrently inhibiting cell death through targets including *Diap1*, *CycE* and *bantam* miRNA [7, 36-39]. The central role of the Hippo pathway as an integrator of other growth-related signals may also contribute to the abundance of

tumor suppressors associated with Yki-driven growth [1, 2, 26]. Mis-regulation of this pathway also contributes to tumor formation in mouse models [40].

The potential of Yki/YAP expression to drive cellular transformation has been highlighted by studies of primary human cells in culture, which have shown that YAP expression is both necessary and sufficient to confer a transformed phenotype involving anchorage independent growth and the ability to form tumors in xenograft models [41, 42]. We therefore consider it likely that the consequence of Yki overexpression predispose the tissue to transformation, allowing identification of a richer repertoire of cooperating factors. Indeed, YAP overexpression has been causally linked to formation of specific human tumors [43, 44]. The Hippo pathway has also been implicated in tumor formation resulting from cytokinesis failure [45] and this has recently been linked to Yki-mediated regulation of *string* (CDC25) expression [46]. The sensitivity of Yki-expressing tissue to tumor formation might be explained by the finding that Yki promotes cell cycle progression at both the G1-S transition (through regulation of *cycE* [7] and at the G2-M transition through regulation of *string*. In contrast, mitogens and growth factors such as EGFR typically induce growth by promoting G1-S, and therefore remain somewhat constrained by the G2-M checkpoint.

While our manuscript was in preparation, another group reported an RNAi screen to identify loci cooperating in tumorigenesis driven by expression in eye discs of the oncogenic activated mutant form of *Ras* [47]. We note that the activated Ras RNAi screen produced over 900 hits, compared with 74 for our EGFR screen, suggesting that the Ras screen was considerably more sensitized. We were surprised to note that there was almost no overlap between the two screens. This suggests that the genetic interactions required to promote tumorigenesis in the context of expression of an activated mutant form of RAS are distinct from those required to promote tumorigenesis in the context of native EGRF overexpression. And perhaps, the differences between

the tissue contexts (eye discs in [47] vs wing discs in our screen). It will be of interest, in future, to learn whether this distinction holds true for factors promoting tumor formation in human cancers that depend on EGFR overexpression vs those dependent on Ras mutants.

To conclude, the results reported here provide an extensive assessment of the genes that can serve as negative regulators of growth that can contribute to the formation of neoplastic tumors *in vivo* in *Drosophila*. In addition to finding genes linked to known growth control pathways, a number of novel connections to Yki and EGFR driven tissue growth have been identified, which merit further investigation in the *Drosophila* genetic model. Exploring the potential relevance of genes identified in this manner to human cancer will involve assessing the correlation of candidate gene expression with clinical outcome across a broad range of cancers (eg [28, 48]), as a starting point to identify biomarkers as well as novel candidate drug targets.

Materials and Methods

RNAi Screens

The KK transgenic RNAi stock library was obtained from the Vienna *Drosophila* RNAi Center (www.vdrc.at) carrying inducible UAS-RNAi constructs on Chromosome II. For each cross, 5 males from the KK transgenic RNAi stock were crossed separately to 10-15 virgins from each of the following three driver stocks: *w**, *ap-Gal4*, UAS-*GFP*/CyO; UAS-*Yki*, *tub-Gal80^{ts}*/TM6B (Yki driver); *w**, *ap-Gal4*, UAS-*GFP*/CyO; UAS-*EGFR*, *tub-Gal80^{ts}*/TM6B (EGFR driver); and *w**; *ap-Gal4*, UAS-*GFP*/CyO; and *w**; *ap-Gal4*, UAS-*GFP*, *Socs36E^{RNAi}*/CyO; UAS-*EGFR*, *tub-Gal80^{ts}*/TM6B (EGFR driver +SOCS36E RNAi).

Virgin female flies were collected over 4-5 days and stored at 18°C in temperature-controlled incubators on medium supplemented with dry yeast, prior to setting up crosses. Virgin

females were mated to KK stock males (day 1) and the crosses were stored at 18°C for 4 days to provide ample time for mating before starting the timed rearing protocol used for the screen. On day 5, the crosses were transferred into new, freshly yeasted vials for another 3 days at 18°C. On day 8, the adult flies were discarded, and larvae were allowed to develop until day 11, at which time the vials were moved to 29°C incubators to induce Gal4 driver activity. Crosses were aged at 29°C for a further 8-9 days, after which larvae were scored for size and wing disc overgrowth phenotypes for Yki and EGFR driver screen crosses. Flies were scored for suppression of the tumor phenotype for the EGFR driver +SOCS36E RNAi crosses (see Supplemental Fig. S1 for the screen design and workflow).

In order to verify the integrity of the driver stocks during the course of the screen, we examined their expression patterns in conjunction with setting up screen crosses each week. For each driver, 2-3 of the bottles used for virgin collection were induced at 29°C for 24 hours and analyzed using fluorescence microscopy for *apterous*-Gal4 specific expression in wandering 3-instar larvae.

Positive hits from the initial screen were retested by setting up 2 or more additional crosses. The hits were scored as verified if 2 out of 3 tests scored positive. Wandering third instar larvae of confirmed positives were imaged and documented using fluorescence microscopy.

Genomic DNA PCR 40D landing site occupancy test

Genomic DNA from a select number of *Drosophila* KK transgenic RNAi library stocks was isolated following a protocol available at the VDRC (www.vdrc.at). The presence or absence of the KK RNAi transgene at the 40D insertion site on the second chromosome was determined by multiplex PCR using the following primers:

40D primer (C_Genomic_F): 5'-GCCCACTGTCAGCTCTCAAC-3'
pKC26_R: 5'-TGTA AACGACGGCCAGT-3'

pKC43_R: 5'-TCGCTCGTTGCAGAATAGTCC-3'

PCR amplification was performed using GoTaq G2 Hot Start Green Master Mix kit (Promega) in a 25 μ L standard reaction mix and the following program: initial denaturation at 95°C for 2 min, followed by 33 cycles with denaturation at 95°C for 15 sec, annealing at 58°C for 15 sec and extension at 72°C for 90 sec. One final extension reaction was carried out at 72°C for 10 min. Reactions were stored at -20°C prior to gel loading. PCR using these primers generate an approximately 450 bp product in case of a transgene insertion or a 1050 bp product in case of no transgene insertion site at 40D.

Screen Database

Results from the three screening projects were added to a screen management database, www.iiserpune.ac.in/rnai/, including images of positive hits and background information such as RNAi line ID, corresponding gene information from the Flybase etc. The database was developed by Livetek Software Consultant Services (Pune, Maharashtra, INDIA).

Pathway and gene set enrichment analysis

Gene set enrichment analysis was performed using genes that upon down regulation induced tumor formation (EGFR, YKI background) or suppressed tumor formation (EGFR+SOCS background). For *D. melanogaster* enrichment analysis all *D. melanogaster* protein coding genes were used as the “gene universe” together with organism specific datasets. For human ortholog enrichment analysis all human protein coding genes were used as the “gene universe” together with organism specific datasets. The algorithm packages and databases used in analysis are listed in Supplemental Tables S2 and S3. Unless otherwise specified, pathway databases included in these packages were used. The KEGG database was downloaded directly from source on 10.10.2018. Organ system specific

and disease related pathway maps were excluded from this analysis. Minimum and maximum number of genes per pathway or gene set, significant criteria, minimum enriched gene count and annotated gene counts for each test and database are indicated in Supplemental Tables S2 and S3. GO results were filtered for level >2, to eliminate broad high-level categories and <10 to minimize duplication among subcategories. A representative term was selected in the cases where identical set of genes mapped to multiple terms within the same database. After filtering, the top 10 terms from each database were used for clustering analysis.

Pathway and gene set enrichment analysis results were visualized as enrichment map with appropriate layout based on gene overlap ratio using igraph. Gene overlap ratio was set as edge width. Edges with low overlap were deleted, filtering threshold was based on a number of “terms” in the results table – from 0 to 50 by 10; increasing filtering thresholds from 0.16 to 0.26 by 0.2. Clusters were detected using “Edge betweenness community” algorithm. Similar biological processes were color-coded.

STRING interaction maps

STRING v10 is a computational tool for protein interaction network and pathway analysis [56]), to identify significant functional clustering among the candidate genes. STRING builds interaction maps by combining experimental data (including protein interaction data) with information about functional associations from text mining. STRING interactome maps were used to search for statistically significant enrichment of KEGG pathways.

Acknowledgements

The professionalism, tireless support and goodwill provided by Snehal Patil, Yashwant Pawar and Bhargavi Naik from the IISER Pune fly facility contributed greatly to the success of the screening projects reported here.

Funding

This work was primarily supported by a Indo-Danish research grant from Department of Biotechnology, Govt. of India to TSS and LSS and from Innovationfund Denmark, Novo Nordisk Foundation NNF12OC0000552 and Neye Foundation to SMC. JC Bose Fellowship and grant from Department of Science & Technology, Govt of India to LSS. We thank other members of all the laboratories for critical input.

Figure legends

Figure 1: tumor formation/suppression visualized in intact larvae

(A) Larvae co-expressed UAS-GFP with the indicated transgenes to permit visualization of the imaginal discs in the intact animal. All samples carried the *ap*-Gal4 driver and UAS-GFP. In addition, they carried either a second copy of UAS-GFP or one of the following: UAS-Yki, UAS-EGFR or UAS-EGFR+UAS-SOCS36E-RNAi.

(B) Table summarizing the number of interacting RNAi lines identified in the three large-scale screens.

Figure 2: Summary of pathway enrichment analysis of fly genes identify in the *in vivo* screens reported here.

(A, C, E) The results of the pathway and gene set enrichment analysis are shown as graphical interaction maps. Each node represents a significantly enriched term or pathway from the GO, KEGG, Reactome and Panther databases (Table S2). Color-coding indicates functionally related groups of terms. Lines indicate genes shared among different terms. (B, D, F) show the individual genes associated with functionally enriched cluster.

Author contributions

MC, TSS and LSS conceived, designed and coordinated the study.

MC, MGN, JSP, MK designed various experiments and standardised all protocols. MC carried out all experiments.

MC and DK analysed the TCGA and METABRIC data MC

and LSS drafted the manuscript.

All authors gave final approval for publication and agree to be held accountable for the work performed therein.

Abstract

PTPN11/SHP2, a non-receptor protein tyrosine phosphatase is a prominent target of the receptor tyrosine kinase that participates in positive feedback signalling of the human epidermal growth factor receptors and helps in growth and migration. PTPN11/SHP2 is widely believed to be an oncoprotein, although it's possible tumor-suppressor role is also reported. Our analysis of breast cancer metadata shows, PTPN11/SHP2 copy number loss in luminal A subtype is correlated to poor disease-specific survival and late-stage cancer at diagnosis. Analysis of the level 4 Reverse Phase Protein Array (RPPA) data available on the TCGA database resulted in positive correlations between the lower expression levels of constitutively active variant, the phospho-SHP2-Y542, of PTPN11/SHP2 and larger tumor size and lymph node positivity. We experimentally examined possible negative regulation of growth by PTPN11/SHP2 using MCF10A, a normal breast epithelial cell line. Knock-down of PTPN11/SHP2 resulted in increased cell migration, cell shape changes to mesenchymal morphology, and increased survival in cells treated with epirubicin, a DNA-damaging drug. However, it did not alter the rate of cell proliferation. It is possible that PTPN11/SHP2 might function as a tumor suppressor by potentiating proliferating cells with increased cell migration and resistance to apoptosis.

Statement of Significance

Molecules like *PTPN11/SHP2*, among many others that show dual specificity in tumorigenesis in the same tissue depending on the upstream signaling cues, present challenges in the field of targeted drug therapy. This study puts forth the importance of understanding the mechanism of one of the two outcomes and thereby helps better clinical management of a subgroup of cancer.

Introduction

Src homology phosphatase 2 (SHP2) is encoded by the PTPN11 gene. PTPN11/SHP2 has two N terminal SH2 domains, N-SH2 and C-SH2, a middle phosphatase domain, and a C terminal proline-rich tail with tyrosine 542 and 580 which are phosphorylated for catalytic activation of the phosphatase by Src Kinases (Neel, Gu, and Pao 2003; Zhao, Sedwick, and Wang 2015). Characterization of phosphorylation profile regulated by PTPN11/SHP2 activity and its localization has identified 53 different proteins including ERK, P38, and many adhesion kinases (Corallino et al. 2016).

PTPN11/SHP2 is one of the few phosphatases demonstrated to have oncogenic properties. Over-expression of PTPN11/SHP2 is shown to correlate to aggressive clinical manifestations of gastric cancer (Kong et al. 2017), hepatocellular carcinoma (Han et al. 2015), laryngeal carcinoma (Gu et al. 2014), small cell lung cancer (Yang et al. 2017), thyroid cancer (Hu et al. 2015), ovarian cancer (Hu et al. 2017), glioblastoma (Sturla et al. 2011), colorectal cancer (Yu et al. 2011), pancreatic ductal adenocarcinoma (Zheng et al. 2016) and oral cancer (Xie et al. 2014). Its tumorigenic function is known to be associated with the activation of ERK and PI3-AKT pathways (Aceto et al., 2012 and Zhang et al., 2016). A contrasting tumor suppressor role is also reported for PTPN11/SHP2 in hepatocellular cancer (Bard-Chapeau et al., 2011) and oesophageal squamous cell cancer (Qi et al., 2017), which is mediated by the dephosphorylation of pSTAT3.

In the context of breast cancer, while PTPN11/SHP2 expression levels do not correlate to any intrinsic molecular subtype, its overexpression is associated with the poor overall survival in ER-positive-Ki67 low, Luminal A patients and ER-positive-Ki67 high, Luminal B/HER⁺ patients (Muenst et al. 2013). Furthermore, PTPN11/SHP2 is reported to repress let-7 miRNAs in HER2 overexpressing breast epithelial cells (Aceto et al. 2012). Increased co-expression of PTPN11/SHP2 and EGFR is also correlated to basal-like and triple-negative breast cancer (Matalkah et al. 2016). Breast cancer is one of the well-studied cancers, both at

the clinical and the molecular levels. Two major cancer databases, the METABRIC (specific to breast cancer) and TCGA, both house high quality datasets for breast cancer. Using those databases and experimental validation, here we report our results of the study exploring possible tumor suppressor role for PTPN11/SHP2 in the context of breast cancer.

In contrast to earlier reported oncogenic role in breast cancer, our analysis of breast cancer meta data using both TCGA and METABRIC databases indicate a tumor-suppressor role for PTPN11/SHP2. We further experimentally validated this observation using MCF10A, a non-transformed breast epithelial cell line. siRNA mediated knockdown of PTPN11/SHP2 in MCF10A promotes hallmarks of cancer like increased cell migration and decreased chemosensitivity to epirubicin, although it did not affect cell proliferation.

Results

Clinical Correlations of PTPN11/SHP2 copy number changes in Luminal A Subtype: We

examined the correlation of PTPN11 copy number status with clinical parameters across the PAM50 subtypes of breast cancer (Bernard et al. 2009). We did not include a subset of patients with claudin-low status for our analysis as it was not defined in the PAM50 classification. We observed a significant association of PTPN11/SHP2 to certain clinical parameters within the Luminal A subtype in the METABRIC database. Copy number loss for PTPN11/SHP2 was correlated to late-stage cancer (Figure 1A) and nodal positivity (Figure 1B), but not to the age of patients at diagnosis (Fig. 1C), or their tumor size (Fig. 1D) and grade (Fig. 1E). More importantly, copy number loss was significantly associated with the poor disease-free survival (Fig. 1F) in Luminal A subtype of the breast cancer.

Clinical Correlation of Phospho (tyrosine 542) PTPN11/SHP2 protein expression in Luminal A subtype

To re-confirm our gene-level observation described above at the protein level, we examined if the correlations between phospho-SHP2 (functionally active form of the protein) and the clinical parameters using the proteome data available in the TCGA breast cancer database. We grouped Luminal A breast cancer patients into two groups, those expressing high (above 3rd quartile) and low (below 1st quartile) levels of phospho-SHP2. Lower levels of expression of phospho-SHP2 protein correlated to larger tumor size (Fig. 2A) and nodal positivity (Fig. 2B), while there was no significant correlation to age (Fig. 2C) of the patients at first diagnosis or metastasis (Fig. 2D) and stage (Fig. 2E) of the cancer. Based on these two observations, we hypothesized that PTPN11/SHP2 may function as a tumor suppressor possibly under specific contexts, perhaps those that are associated specifically with the Luminal A subtype of breast cancer.

Effect of the knockdown of PTPN11/SHP2 on the proliferation of MCF10A cell line Knockdown of PTPN11/SHP2 in luminal A cell line, such as T47D, has been reported to decrease migration rate and EMT (Sun et al. 2017), while inhibition of PTPN11/SHP2 in luminal B cell line, MCF7, decreases cell growth (Li et al. 2014). This is in accordance with the oncogenic function of PTPN11/SHP2. However, as described above we observed that lower levels of phospho-SHP2 are associated with larger tumor size in luminal A subtype of breast cancer patients. We sought to verify possible tumor suppressor role of PTPN11/SHP2 by studying the effects of its loss in the transformation of, otherwise, normal breast epithelial cells. Using normal cells was important to examine the molecular context of its tumor suppressor role unperturbed by hormonal receptor signaling. We silenced PTPN11/SHP2 in MCF10A, a non-transformed breast epithelial cell line. We successfully knocked down PTPN11/SHP2 in

Negative regulation of growth by PTPN11/SHP2

Chakraborty et al. 2020

the monolayer culture of MCF10A with two independent siRNAs (hereafter referred as PTPN11/SHP2#si18 and PTPN11/SHP2#si19). We achieved 50-70% depletion of SHP2 protein (Suppl. FigS1A, B) and 80-90% depletion of PTPN11 mRNA expression (Suppl. FigS1C) in transfected MCF10A cells. First, we examined effects on proliferation and survival of MCF10A cells. We used the proliferation marker Ki67 to monitor rate of cell proliferation. We did not observe any significant change in the proliferation index of MCF10A cells due to the knock-down of PTPN11/SHP2 (Fig. 3A, B). We also examined degree of survival of PTPN11/SHP2-depleted cells by MTT assay. We measured cell survival at 72 hours (Day 0), 96 hours (Day 1), 120 hours (Day 2), 144 hours (Day 3) of first transfection. We did not observe any effect on the survival of non-transformed MCF10A breast epithelial cells (Fig. 3C, D).

Effect of PTPN11/SHP2-depletion on cell number and cell size

As lower levels of phospho-SHP2 is correlated to larger tumor size (Fig. 2A), we next examined the effect of knockdown of PTPN11/SHP2 on cell size and cell number. Here too we did not observe any effect (Fig. 3E, F). In Summary, we did not observe any significant change in any of the growth parameters of MCF10A due to the knockdown of PTPN11/SHP2 in MCF10-A cells.

Effect of PTPN11/SHP2-depletion on cell cycle profile

PTPN11/SHP2 is known to regulate cell cycle checkpoints at G1-S transition (Tsang et al. 2012), G2-M phase (Yuan et al. 2005), and transition from metaphase to anaphase (Liu, Zheng, and Qu 2012) upon DNA damage. We did not observe any effect on the cell cycle pattern in MCF10A cells depleted for PTPN11/SHP2 (Fig. 4). We also assessed the effects of the knockdown of PTPN11/SHP2 in the background of induced DNA damage (using epirubicin:

Negative regulation of growth by PTPN11/SHP2

Chelladurai et al. 2020

also see below). We did not observe changes in cell cycle patterns upon epirubicin treatment of MCF10A cells in the background of PTPN11/SHP2 knockdown (Suppl. Fig. S2).

Effect of the knockdown of PTPN11/SHP2 on cell migration and invasion

We next assessed the effect of PTPN11/SHP2 knockdown on other hallmarks of cancer such as cell migration using the standard scratch assay and invasion using the transwell invasion assay. We observed that PTPN11/SHP2-depleted cells migrate 25% more in 24 hours of initial scratch (Fig. 5A, B). Interestingly, we also observed a change in cell morphology. Normally confluent monolayer of MCF10A cells appear cobblestone-like, whereas on PTPN11/SHP2-depleted cells acquired mesenchymal or elongated morphology (Fig. 5C). However, we did not observe any change in the invasion capacity (Fig. 5D) of PTPN11/SHP2-depleted cells in either serum-free or the media supplemented with 5% horse serum using both si18 (Figure 5E) and si19 (Fig. 5F).

Effect of the knockdown of PTPN11/SHP2 on epithelial to mesenchymal transition

We examined if the increased cell migration and the mesenchymal morphology of observed in PTPN11/SHP2-depleted MCF10A cells is an indication of epithelial to mesenchymal transition (EMT). We assessed whether depletion of PTPN11/SHP2 affects the expression of mesenchymal markers E-cadherin, N-cadherin, MMP9, Fibronectin and Vimentin. We observed approximately 2-fold increases in MMP9 (Fig. 6A), Vimentin (Fig. 6B) and Fibronectin (Fig. 6C) expression with near significance across both the siRNAs. We did not observe any change in E-cadherin levels (Fig. 6D) and could not detect N-cadherin at the desired molecular size (data not shown). We also examined the levels β -catenin by immunofluorescence, but could not detect any changes either in the nucleus or the cytoplasm

(data not shown). Nonetheless, increased cell migration in the absence of any change in cell proliferation observed in PTPN11/SHP2-depleted cells could be due to increased EMT.

Effect of the knockdown of PTPN11/SHP2 on the sensitivity to chemotherapeutic drugs

PTPN11/SHP2 plays a critical role in cell cycle checkpoint regulation and apoptosis upon DNA damage. PTPN11/SHP2-depletion has been reported to interfere with CHK1 activation and delay in both Cyclin E accumulation and G1-S arrest (Tsang et al. 2012). Moreover, catalytically active PTPN11/SHP2 modulates PLK1 and Aurora B activity to regulate chromosomal alignment, and thereby restoring checkpoint function at metaphase (Liu, Zheng, and Qu 2012). Alternatively, kinase-inactive PTPN11/SHP2 is involved in regulating nuclear Cdc25C translocation to the cytoplasm through 14-3-3 β and inducing G2-M arrest (Yuan et al. 2005). PTPN11/SHP2 is also reported to mediate apoptosis via regulating c-ABL and caspases (Morales et al. 2014; Yuan et al. 2003). We examined the response of MCF10A cells to the treatment with DNA-damaging chemotherapeutic drug in the presence and absence of PTPN11/SHP2. We treated cells with chemotherapeutic drugs like carboplatin, epirubicin, and paclitaxel. Carboplatin inhibits replication and transcription and induces DNA breaks and cell death (Jiang et al. 2015). Epirubicin intercalates between DNA and inhibits DNA and RNA synthesis, it induces double-stranded DNA breaks and cell death (Konecny et al. 2001). Paclitaxel interferes with mitotic spindle assembly and chromosomal segregation and cell death (Jordan and Wilson 2004). We determined the Inhibitory Concentration (IC) 50 of these cell cycle and DNA synthesis interfering drugs. We used concentration in range of 100 μ M to 1000 μ M for carboplatin, 100nM-100 μ M for epirubicin, and 10nM-100 μ M for paclitaxel to optimize the IC50. We observed that MCF10A had high IC50 for carboplatin, while paclitaxel was not effective in at the concentration range tested (Suppl. Fig. S3). IC50 for epirubicin was 1 μ M (Suppl. Fig. S3) and this drug dose was chosen for subsequent experiments. Ability of

epirubicin to introduce double-stranded DNA breaks in MCF10A cells was confirmed by measuring the levels of phosphorylated (of Serine 139) γ -H2AX (Suppl. Fig. S4).

We observed that PTPN11/SHP2-depleted cells show better survival upon epirubicin treatment at 24 hours compared to the normal cells (Fig. 7A, B). We examined if increased viability of PTPN11/SHP2-depleted cells to epirubicin treatment is associated with changes in apoptosis or cell cycle patterns. We observed that PTPN11/SHP2-depleted cells had a 2-fold decrease in early apoptotic cells (Annexin positive), late apoptotic cells (Annexin +PI double- positive) and dead cells (PI-positive) (Fig. 7C, D). However, PTPN11/SHP2-depleted cells did not affect the ploidy or cell cycle pattern when treated with epirubicin (Supplementary Figure 2). Nonetheless, decreased chemosensitivity to epirubicin in PTPN11/SHP2-depleted cells is associated with the inhibition of apoptosis.

In summary, increased cell migration, change in cell morphology, increased EMT and decreased chemosensitivity and apoptosis in response to drug treatment suggest a tumor suppressor role for PTPN11/SHP2, albeit in certain contexts.

Discussion

PTPN11/SHP2, a non-receptor tyrosine phosphatase, participates in positive feedback regulation of EGFR pathway and drive hematologic malignancies and solid tumors including breast adenocarcinoma, prostate adenocarcinoma, lung adenocarcinoma and colorectal cancer (Aceto et al., 2012; Prahallad et al., 2015; Richine et al., 2016; Schneeberger et al., 2015; Zhang et al., 2016). In contrast to its oncogenic role, PTPN11/SHP2, through suppression of the JAK/STAT pathway, seems to function in inhibiting oncogenesis in hepatocellular carcinoma and esophageal squamous cell cancer (Bard-Chapeau et al. 2011; Qi et al. 2017). These observations suggest that PTPN11/SHP2 may function either as an oncogene or a tumor suppressor, perhaps in different cellular and molecular contexts. To verify this, we carried out

Negative regulation of growth by PTPN11/SHP2

Chakraborty et al. 2020

a retrospective investigation of publicly available clinical metadata followed by experimental validation of our hypothesis. The oncogenic function of PTPN11/SHP2 has been reported in the backgrounds of HER2, EGFR, WNT and PI3K-AKT in breast cancer (Aceto et al. 2012; Zhao and Agazie 2015; Zhang et al. 2016).

In our analysis of breast cancer data from METABRIC and TCGA datasets, PTPN11/SHP2 does not appear to affect the clinical outcomes of the HER2-driven breast cancer or the TNBC (data not shown). However, we observed putative tumor suppressor function for PTPN11/SHP2 in Luminal A subtype of breast cancer. The copy number loss of PTPN11/SHP2 in Luminal A subtype of METABRIC cohort correlates to late-stage cancer and poor disease-specific survival. Furthermore, lower levels of expression of Phospho-PTPN11/SHP2 in luminal A correlates to larger tumor size and greater lymph node positivity in TCGA dataset. A detailed pathway enrichment analysis of phosphoproteins in TCGA RPPA Level 4 2015 data when correlated to phospho-PTPN11/SHP2 Y542 expression levels could give us insights into the context in which it may function as a tumor suppressor in the luminal A subgroup of patients in TCGA cohort. As PTPN11/SHP2 is a phosphatase, its phosphoprotein expression rather than gene expression and its implications on proteins and phospho-proteins of cancer patients is relevant in the identification of the upstream cues that is responsible for switching between its dual role in tumorigenesis. TCGA level 4 RPPA data provides the expression of a limited number of 225 protein and phosphoprotein data which could be used to understand the context of PTPN11/SHP2 function.

Experimental validation of our clinical results by transient silencing of PTPN11/SHP2 in non-transformed MCF10A showed that knockdown of PTPN11/SHP2 promotes migration, changes in cell shape to mesenchymal morphology and decreased sensitivity to chemotherapeutic drug, epirubicin, by decreasing apoptosis. Mechanistic understanding of the tumor suppressor role of PTPN11/SHP2 from our study suggests regulation of EMT molecules

Negative regulation of growth by PTPN11/SHP2

Chakraborty et al. 2020

to limit transformation and migration of breast epithelial cells. We also report the involvement of PTPN11/SHP2 in sensitizing MCF10A cells to chemotherapeutic drugs such as epirubicin by regulating apoptosis. The phosphatase activity of nuclear PTPN11/SHP2, in response to DNA damage, in embryonic fibroblast cells activate c-ABL kinase via its SH3 domain, which in turn stabilizes P73 and allow transcription of target genes including P21^{Cip1} and BAX to initiate apoptosis (Yuan et al. 2003). PTPN11/SHP2 is also reported to mediate Rb/E2F associated apoptosis possibly by caspase8 and caspase3 activation along with PTP-1B and PTEN (Morales et al. 2014). We did not observe any change in BAX (Suppl. FigS5) or caspase 3 expression (data not shown) in PTPN11/SHP2-depleted cells with or without drug treatment. In summary, while PTPN11/SHP2 may activate apoptosis when cells are subjected to severe DNA damage (such as drug treatment), understanding the precise molecular pathway/s needs further analysis. Being a phosphatase, PTPN11/SHP2 may not behave like a classical tumor suppressor. It may function in a dose-dependent manner. Suboptimal levels above wildtype such as gain of copy number could allow it to behave differently, depending on upstream molecular cues/contexts.

Methods

Clinical data analysis

For all analyses, data from METBRIC 2012 and TCGA 2015 was used. METABRIC data was downloaded from cbioportal (Cerami et al. 2012) and TCGA GRCh38 data from the GDC data portal using the GenomicDataCommons R tool (Morgan M, Davis S (2019).

GenomicDataCommons:NIH/NCIGenomicDataCommonsAccess.

(<https://bioconductor.org/packages/GenomicDataCommons>,

<http://github.com/Bioconductor/GenomicDataCommons>).

Negative regulation of growth by PTPN11/SHP2

Chakraborty et al. 2020

The TCGA RPPA level 4 data was downloaded from FireBrowse (firebrowse.org). The clinical metadata analysis was performed using R (version 3.6.1, platform x86_64-w64-mingw32/x64). Packages used for analysis include `survminer_0.4.6`, `ggpubr_0.2.3`, `magrittr_1.5`, `survival_2.44-1.1`, `forcats_0.4.0`, `stringr_1.4.0`, `purrr_0.3.3`, `readr_1.3.1`, `tidyr_1.0.0`, `tibble_2.1.3`, `ggplot2_3.2.1`, `tidyverse_1.2.1`, `dplyr_0.8.3`. For TCGA RPPA data analysis additional packages `Hmisc_4.2-0`, `Formula_1.2-3`, `lattice_0.20-38` was used. Kruskal-Wallis, Wilcoxon, and log-rank test were used for statistical analysis, $p < 0.05$ was considered significant.

Cell culture

MCF10A cells were harvested in DMEM media (#10566-016, ThermoFisher Scientific) with 100units/ml of Penstrep (#15140122). Growth media was supplemented with 5% horse serum (#26050088, GIBCO) and 20ng/ml of EGF (#E9644, Sigma), 0.5ug/ml of hydrocortisone (#H0888-5G, Sigma), 100ng/ml of cholera toxin (#C8052-1MG, Sigma) and 10ug/ml of insulin (# I1882-100MG, Sigma).

Mycoplasma Testing

Cells were routinely checked for mycoplasma contamination and cleared (if any) using LookOutO mycoplasma elimination Kit (#MP0030).

Cell Passaging

Monolayer MCF10A cells from passage 23 to passage 32 were used for all experiments. Media from monolayer cells was aspirated, rinsed with DPBS (3D8537-500ML), and trypsinised for 10-15 mins using 0.05% Trypsin EDTA (# 25300054, ThermoFisher Scientific). The cells were incubated at 37°C, 5% CO₂; dissociated cells were resuspended in DMEM with 10% horse serum and centrifuged at 2000 RPM, 6mins. Cells were seeded in a 1:4 ratio and they reach confluency of 80-90% by 3-4 days. The cells were cultured for 6 passages at any time and discarded.

siRNA transfection

Cells were seeded at 0.16 million per 6 well and scaled down according to the plate used. 24 hours post-seeding, cells were rinsed in DPBS and grown in serum-free media (growth media without horse serum and pen strep) 24 hours before transfection. Cells were transfected using lipofectamine RNAi max (#13778150, Thermofisher Scientific) and two independent Accell siRNA-PTPN11, Targeted Region: 3'UTR (A-003947-18-0005, denoted as **#18** and A-003947-19-0010, denoted as **#19**) at 500nM and 1uM concentrations, respectively, in serum-free media. The equimolar concentration of siLACZ was used as control for each. 24 hours post-transfection, the transfection media was aspirated out and cells were replenished with growth media. Following 48 hours of transfection, growth media was aspirated out and cells were rinsed in serum-free media 1 hour before the second shot of transfection. Cells were again transfected and 48 hours post-second transfection all experiments were carried out. All experiments were carried out using both the siRNA, data for si18 is shown. Knockdown efficiency was 60-70% estimated at the protein level. The sequences for the siLACZ used are: LACZ: 5'-CGUACGCGGAAUACUUCGA-3'

3'-GCAUGCGCCUUAUGAAGCU-5'

(dTdT overhang)

RNA isolation and RT-qPCR

Total RNA was isolated using TRIzol reagent (Sigma) and estimated using nanodrop. 500ng RNA was converted to cDNA with superscript III first-strand synthesis for RT-PCR (#1191-7010). Synthesized RNA was diluted in DNase free water and mixed with SYBR fast qPCR master mix from Kappa biosystems (KK4601) and processed using the BioRad CFX96 real-time qPCR system. All mRNA quantification of the target gene was optimized to housekeeping control, GAPDH, or an average of housekeeping controls (ACTB, RPLPO, or PUM1) and quantitated using the $\Delta\Delta$ CT method or average RNU. Primer sequences used are as follows:

| Gene | Sequence |
|---------|-----------------------------|
| PTPN11 | F: CGGAAAGTGTGAAGTCTCCAG |
| | R: GCGGGAGGAACATGACATC |
| GAPDH | F: AATGAAGGGGTCATTGATGG |
| | R: AAGGTGAAGGTCGGAGTCAA |
| B-Actin | F: TTCCTGGGCATGGAGTC |
| | R: CAGGTCTTTGCGGATGTC |
| RPLPO | F: GGCTGTGGTGCTGATGGGCAAGAA |
| | R: TTCCCCCGGATATGAGGCAGCAGT |
| PUM1 | F: CCGGAGATTGCTGGACATATAA |
| | R: TGGCACGCTCCAGTTTC |

Cell lysis and Western Blot Hybridization

Cells were washed three times in ice-cold DPBS, followed by addition of cell lysis buffer (RIPA: 20mM Tris (pH=8), 420mM NaCl, 10% glycerol, 0.5% NP40, 0.1mM EDTA, water to add up the volume) and incubated in ice for 40 mins to allow complete lysis. The lysates were collected using a cell scraper and centrifuged at 13,000 RPM, 15mins. The supernatant was collected in labelled tubes and mixed with 1X lamelli buffer and heated at 95 degrees, 5mins. SDS PAGE was run at 70V in stacking gel and at 100V in resolving gel and then transferred to the PVDF membrane for 90mins at 90V. The transferred membrane was blocked in 5% BSA or 5% Milk for 1 hour followed by the addition of primary antibody in 2% BSA or 2% Milk and then incubated overnight at 4 degrees C. Following day, the primary antibody was removed and the membrane was washed thrice with (0.1%) TBST. Secondary antibody conjugated to HRP was added in 1:10,000 dilutions in 2% BSA or 2% milk and incubated for 1hour at room temperature. Secondary antibody incubation was followed by 0.1% TBST wash and developed using an ECL kit (Merck). Densitometry analysis was used for quantitation of protein expression levels using Image J. The expression levels were normalized to housekeeping genes, GAPDH, or β Actin.

Cell Number

PTPN11/SHP2 knocked down cells were trypsinised and centrifuged at 2000 RPM, 6mins. The cell pellets were dissolved in 1ml growth media and counted using a haemocytometer.

Cell Size and Cell Morphology

Immunofluorescence images were captured at 63x oil objective in Leica SP8 confocal microscope. ROI of each cell was calculated for the area using Image J. A total of 100 cells across 3 biological replicates were analysed. At least 60% of the cell population were imaged and analysed for change in morphology.

MTT assay

10ul of 5mg/ml of MTT (#M5655-100MG) was added to 100ul of cells in growth media. Growth media alone as used as blank. We incubated the cells after MTT addition for 3.5 hours at 37°C and aspirated the media with MTT. Post 3.5 hours, 100ul of DMSO (#D2438-50ml, Sigma) added, kept in a shaker for 5mins and measured absorbance at 570nm and 650nm. **Immunofluorescence**

microscopy

Growth media was aspirated and cells were rinsed in DPBS. Cells were fixed with 4% PFA (Sigma) for 10mins. PFA was aspirated and cells were rinsed again in PBS, for 10mins each, repeated thrice. Cells were permeabilised and blocked with 2% FBS in 0.03% PBST (30ul Triton X (Sigma) in 10ml DPBS) for 30mins. Following permeabilization, the primary antibody was diluted in DPBS before adding and incubated overnight at 4 degrees C. Following primary incubation, cells were rinsed in 0.05% PBST (5ul Tween20 (Sigma) in 10ml DPBS) for 10mins each, repeated thrice. Cells were mounted in prolong gold Antifade DAPI or incubated in DAPI (1:1000) for 1 min and washed with DPBS before mounting (#P36931 and D9542).

Wound healing/Scratch assay

Monolayer cells were treated with 10ug/ml of mitomycin C (Sigma M4287) for 2 hours before initial scratch. Cells were wounded using a 10ul sterile micropipette tip. Scratch was rinsed with DPBS, following which growth media were added to wells. Cells were acclimatized at 37°C for 10mins before recording a 0-hour wound distance. 3 areas per sample were recorded.

Negative regulation of growth by PTPN11/SHP2

Chakraborty et al. 2020

24 hours post initial wound, images of the same area recorded for 0-hour were measured with EVOS FL Auto. Wound distance was calculated using ImageJ, an average of 12 data points per sample were used for all analyses. 24-hour wound distance was subtracted from 0-hour wound distance and normalized to 0-hour wound distance (as the initial scratch was not the same across samples) and multiplied by 100 (percentage wound closure). We performed a double normalization by subtracting the percentage wound closure of every sample from its control siLACZ. Data points were plotted in GraphPad prism.

Transwell invasion assay

K913-24 transwell assay kit was used to compare the invasion capacity of PTPN11/SHP2- depleted cells. For invasion assay, we serum-starved PTPN11/SHP2-depleted cells at 72 hours of knockdown (18-24 hours before invasion assay). Cells were then trypsinised and seeded at a concentration of 0.5-1 million cells/collagen-coated wells. 24 hours later, cells that migrated to the lower chamber were assayed using manufacturers protocol.

Flow cytometry and cell cycle analysis

Cells were trypsinised and centrifuged at 2000 RPM, 6mins. The cell pellet was washed with DPBS by gentle vortexing and centrifuged at 2000 RPM, 6mins. The step was repeated twice. Following DPBS wash, cells were fixed in ice-cold 70% ethanol for 30 mins. Post fixation, samples were centrifuged at 2000 RPM, 6mins. The cell pellet was washed with DPBS and centrifuged again at 2000 RPM for 6mins. Cells were treated with RNase (DS0003) (to remove any RNA contamination) for 5mins in ice. Following incubation, 5ul of Propidium Iodide in a 1million cells/sample was added 5mins before acquisition. The cell cycle profiles were acquired using BD FACS Calibur and BD FACS Celesta. Analysis was performed in BD software.

Apoptosis

Following epirubicin treatment for 24 hours, cells in media supernatant was collected in labelled tubes. Attached cells were trypsinised and collected in the respective tube and centrifuged at 2000 RPM, 6mins, 4°C. Cells were washed with ice-cold DPBS and centrifuged at 2000 RPM, 6mins. Cell pellet was dissolved in ice-cold 90ul 1X Annexin binding buffer and added 5ul of Annexin V and 5ul Propidium iodide. The samples were incubated for 5mins with 0.25mM CaCl₂ in dark and imaged and analysed in Operetta, Perkin Elmer.

Antibodies: The following antibodies were used,

| Antibody Name | Catalog number | Working Conc. | Dilution in |
|--|------------------------------|-------------------|----------------|
| SHP-2 (D50F2) Rabbit mAb | 3397 | 1:1000 | 2% BSA |
| Phospho-SHP-2 (Tyr542) Antibody rabbit mAb | 3351 | 1:1000 | 2% BSA |
| Anti- β H2A.X (phospho S139) antibody [9F3] | ab26350 | 1:10,000 | 2% Milk |
| Anti-Ki67 antibody [EPR3610] | ab92742 | 1:100 | DPBS |
| Anti-MMP9 antibody [EP1254] | ab76003 | 1:10,000 | 2% BSA |
| Purified Mouse Anti-E-Cadherin Clone 36/E-Cadherin (RUO) | 610181 | 1:1000 | 2% BSA |
| Purified Mouse Anti-N-Cadherin Clone 32/N-Cadherin (RUO) | 610920 | 1:1000 | 2% BSA |
| Purified Mouse Anti-Fibronectin Clone 10/Fibronectin (RUO) | 610077 | 1:1000 | 2% BSA |
| β -catenin | #9562S | 1:1000/1:500 | 2% BSA or DPBS |
| Propidium Iodide - 1.0 mg/mL Solution in Water | P3566 | 1ul/million cells | DPBS |
| Annexin V, Alexa Fluor® 488 Conjugate | A13201 | 5ul/million cells | DPBS |
| Vimentin | V9 clone, Santacruz | 1:1000 | 2% BSA |
| β -actin | Santacruz | 1:1000 | 2% BSA |
| GAPDH | RG000110 | 1:2500 | 2% Milk |
| Secondary Anti-Rabbit Alexa 568 | Invitrogen, Molecular probes | 1:10,000 | DPBS |
| Secondary Anti-Rabbit Alexa 488 | Invitrogen, Molecular probes | 1:10,000 | DPBS |
| Secondary Anti-Rabbit HRP | Invitrogen, Molecular probes | 1:10,000 | 2% Milk/BSA |
| Secondary Anti-Mouse HRP | Invitrogen, Molecular probes | 1:10,000 | 2% Milk/BSA |

Statistical Analysis

Column statistics (GraphPad Prism) was used for statistical analysis, $p < 0.05$ was considered significant.

Unpaired T-Test was used for survival assay. P values are flagged as * ($p < 0.05$),

** ($p < 0.01$) and *** ($p < 0.001$).

Figures and Figure Legends

Figure 1

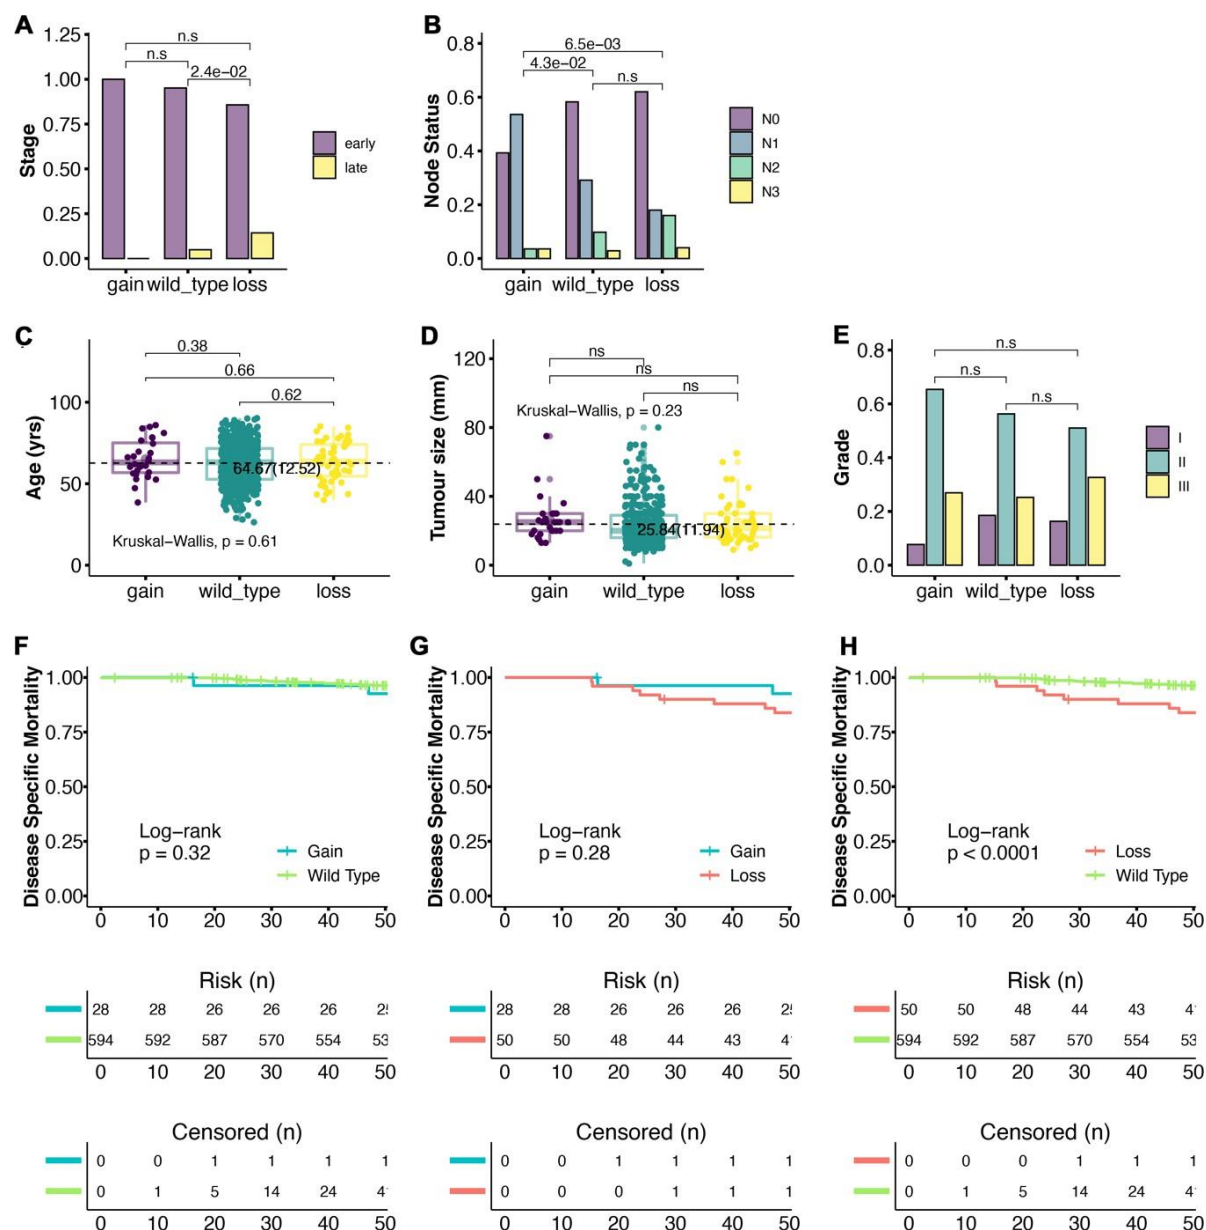

Figure 1: Clinical association of PTPN11/SHP2 copy number changes in Luminal A Subtype of breast cancer. Correlation between the Copy number of PTPN11 and certain clinical parameters were analyzed using the data available in the METABRIC database on Luminal A subtype of breast cancer. (A-E) Statistically significant correlation was observed for late-stage cancer (A) and nodal positivity (B), but not to the age of patients at diagnosis (C), tumor size (D) or the grade (E). In case of nodal positivity, protective role of high copy number

Negative regulation of growth by PTPN11/SHP2

Chakraborty et al. 2020

of PTPN11 was obvious when compared to the wildtype or the loss in the copy number. (F-H) Correlations between Copy number differences between gain vs wt (F), gain vs low (G) and low vs wt (H) for the disease-free survival at 4 years of follow up. Loss of copy number is significantly associated with poor disease-free survival (H).

Figure 2

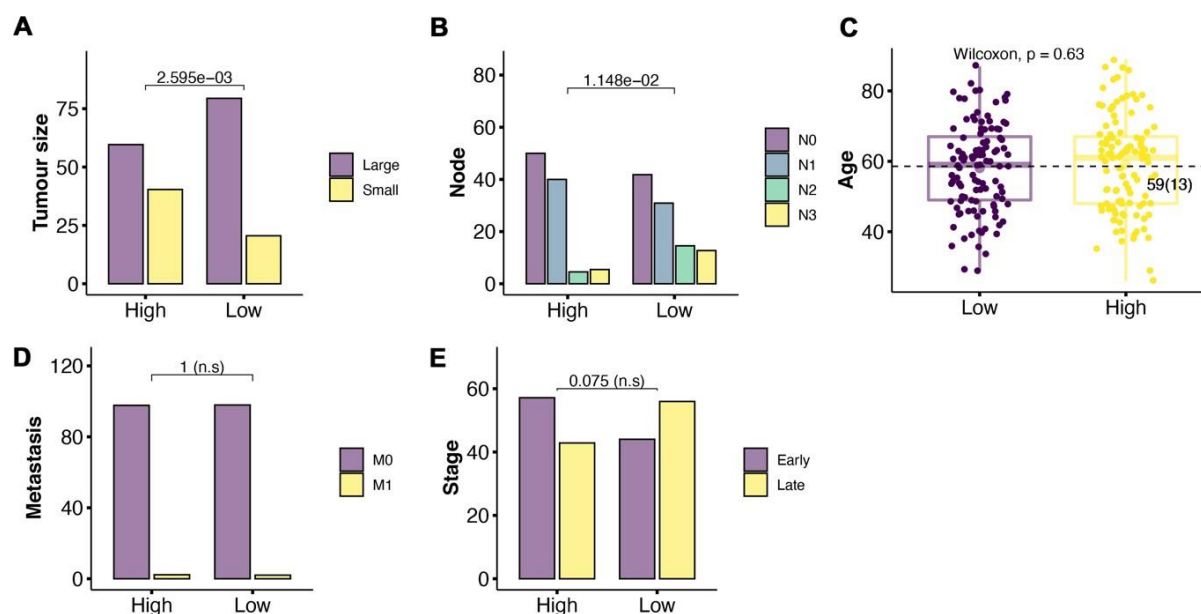

Figure 2: Clinical Correlation between Phospho-PTPN11/SHP2 protein expression and clinical phenotypes of Luminal A patients at diagnosis. We used proteomic data from the TCGA database to examine the correlations between the functionally active phospho-PTPN11/SHP2 to the clinical manifestations of Luminal A patients of breast cancer. Significant association is observed between Low levels of Phospho- PTPN11/SHP2 and larger tumor size (A) and LN2 and LN3 positivity (B). No such correlations were observed for age (C), metastasis (D) or the stage of the cancer (E).

Figure 3

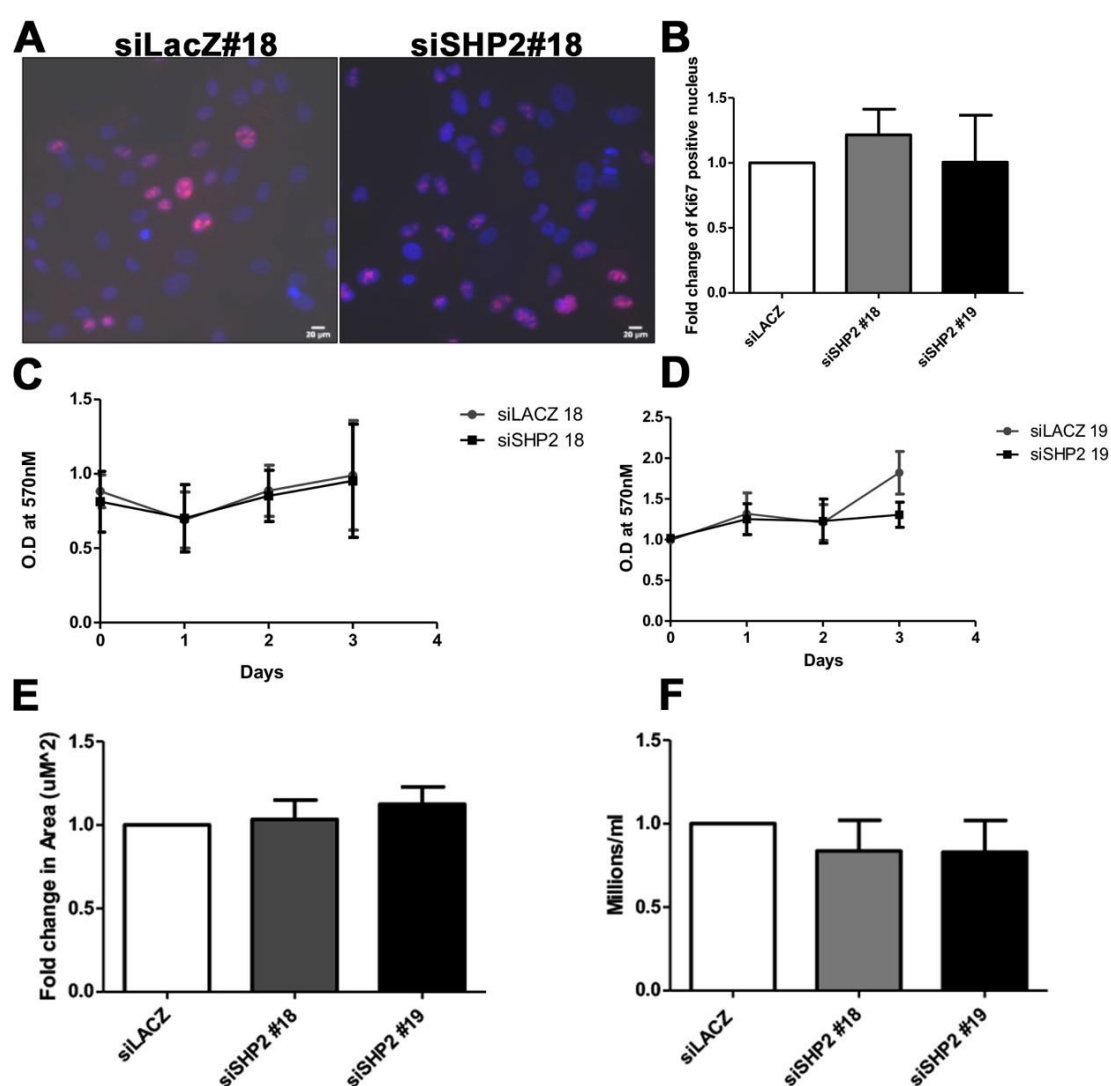

Figure 3: Effect of the knockdown of PTPN11/SHP2 on cell proliferation, survival, size and number. (A-B) Cell proliferation was measured in control and experimental MCF10A cells stained with the proliferation marker Ki67. Representative images of Ki67-stained cells are shown in A, both control (siLacZ#18) and the experimental (siSHP2#18). (B) shows the quantitation of change in the number of Ki67-expressing cells the control and experimental cells. We did not observe any change in Ki67 value. Images and the quantitation are shown for si18, while the observation is reconfirmed with si19 too. (C-D) Cell survival was measured using O.D values normalized to day 0 and plotted for 4 days of growth. For each biological replicate, we had 4 technical replicates. We did not observe any change in cell survival for any

Negative regulation of growth by PTPN11/SHP2

Chelladurai et al., 2020

of the 4 days of our assays using both siRNA 18 and 19. (E) Cell size was measured by immunostaining of β -Catenin, an adheren junction protein to mark the borders of the cell. The cell size was quantitated by measuring the area of cells (area in μm^2). At least 100 cells across 5 fields and 3 biological replicates were recorded for quantitation. There was no change observed in cell size. (F) Quantitation of cell number by Hemocytometer count. Here too we did not observe any change due to the knockdown of PTPN11/SHP2.

Figure 4

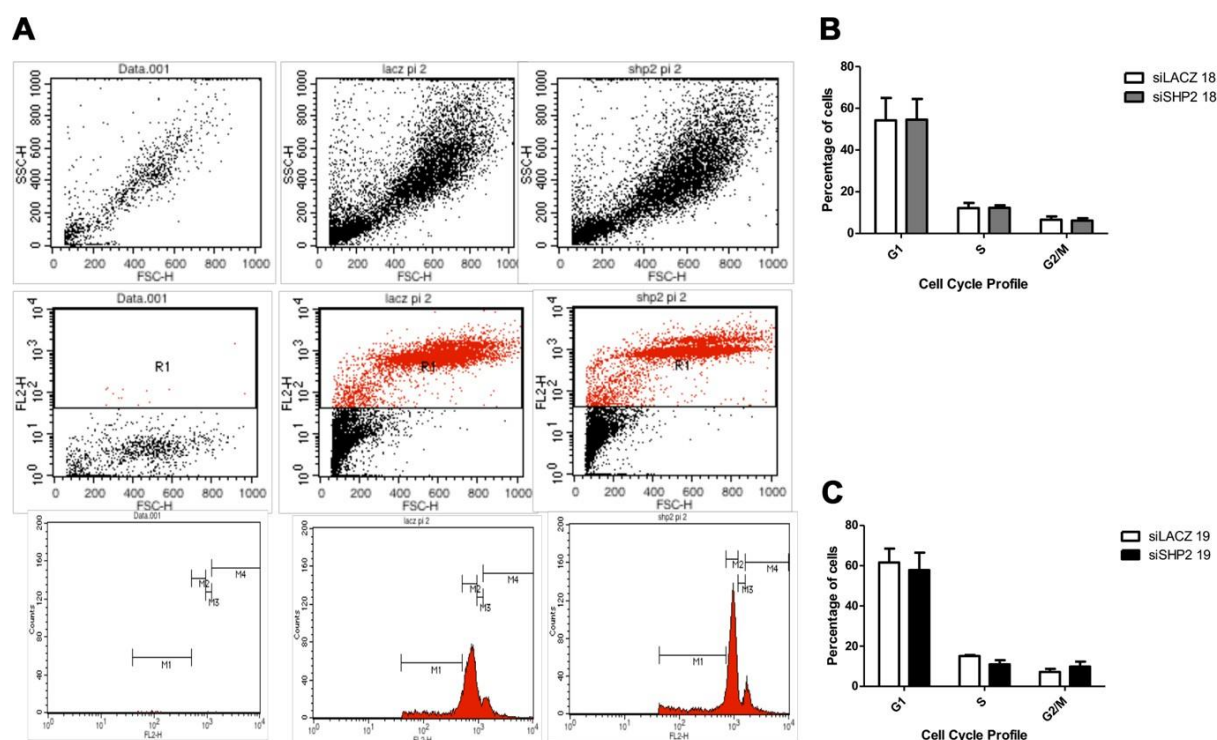

Figure 4: Effect of the knockdown of PTPN11/SHP2 on cell cycle profile of MCF10A cells.

(A) FACS analysis showing cell cycle pattern of control and PTPN11/SHP2-depleted MCF10A cells, with scatter plots showing selected population for analysis and histogram showing cell cycle phases denoted with gate, M. Flow analysis is shown only for si18, however, data was reconfirmed with si19. M1 which is the sub G1 population was not quantitated in our analysis. For the cell cycle pattern, 10,000 cells were recorded by Flow cytometry after PI staining. (B) and (C) show quantitation of cell count in G1 (M2), S (M3), and G2/M (M4)

phases of the cell cycle (N=5). No significant changes are observed for any of the cell cycle phases in PTPN11/SHP2-depleted cells.

Figure 5

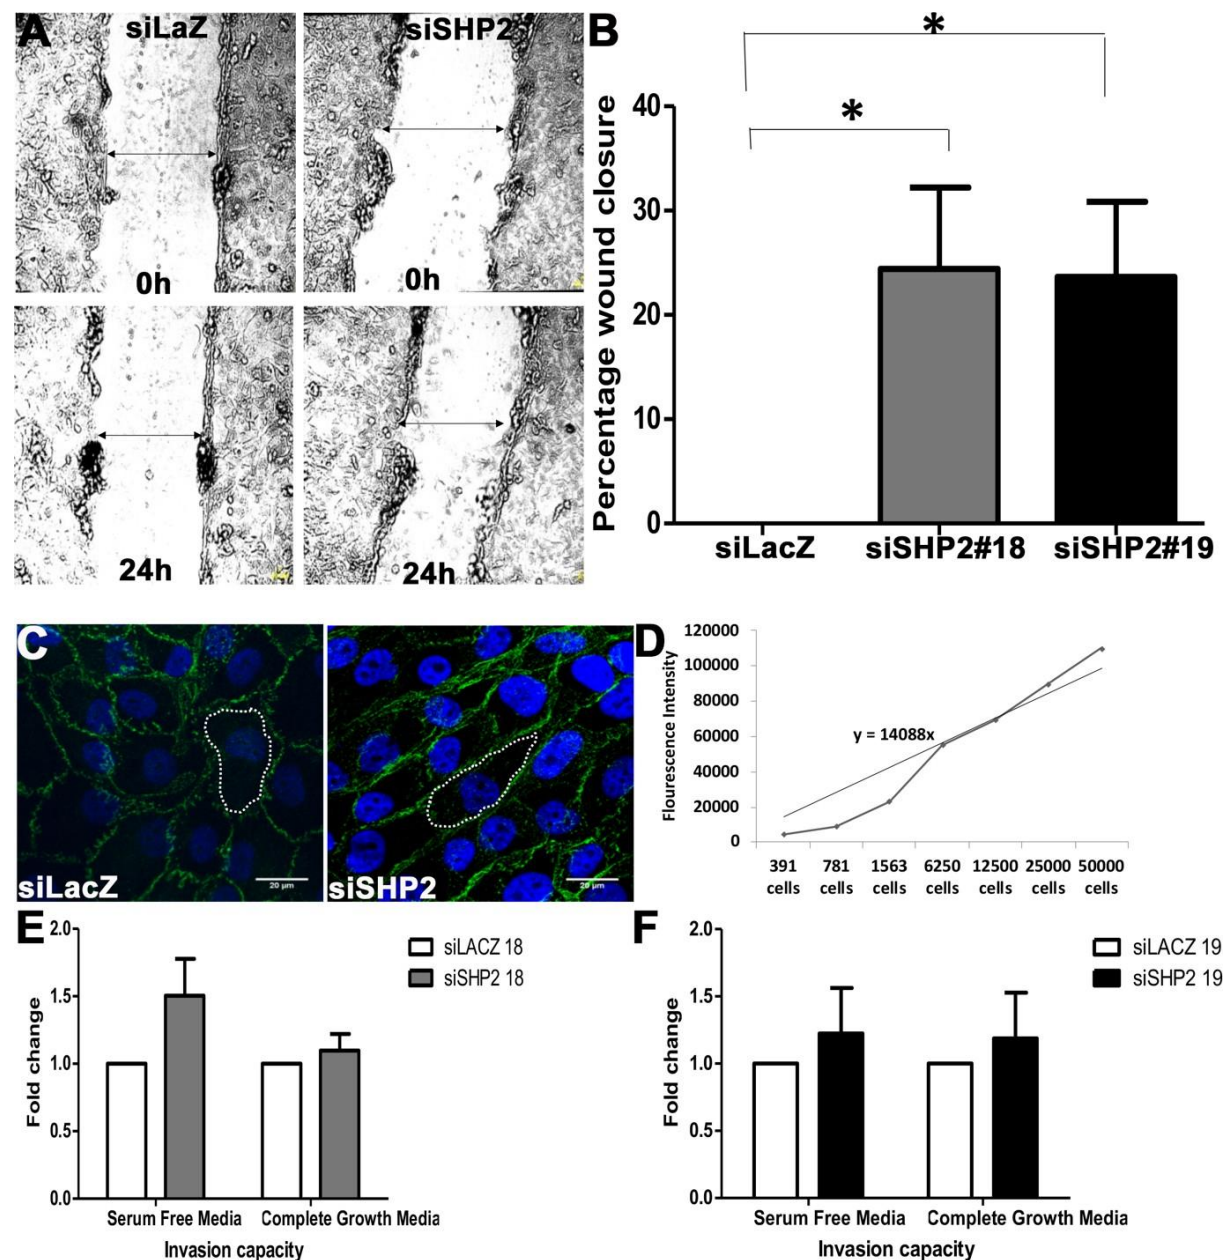

Figure 5: Knockdown of PTPN11/SHP2 increases the rate of cell migration and invasion, which is associated with changed cell morphology. (A) Scratch assay showing the initial wound at 0 hour and gap closure post 24 hours of scratch (shown by arrow) of normal MCF10A cells (siLacZ control) and PTPN11/SHP2-depleted cells (siSHP2). (B) Quantitation of the

Negative regulation of growth by PTPN11/SHP2

Chakraborty et al., 2020

percentage wound closure normalized to control. Both siSHP2#18 and 19 show significantly faster wound healing. (C) MCF10A cells stained with β -catenin (Green) and DAPI (Blue). White inset used to show the change in morphology from cobblestone (in siLacZ control cells) to mesenchymal shape (in PTPN11/SHP2-depleted cells). (D) Standard curve showing fluorescence intensity versus cell number for the calibration of the transwell invasion assay Biovision kit. (E, F) The knockdown of PTPN11/SHP2 do not cause any significant changes in the invasion capacity through the matrigel coated transwell.

Figure 6

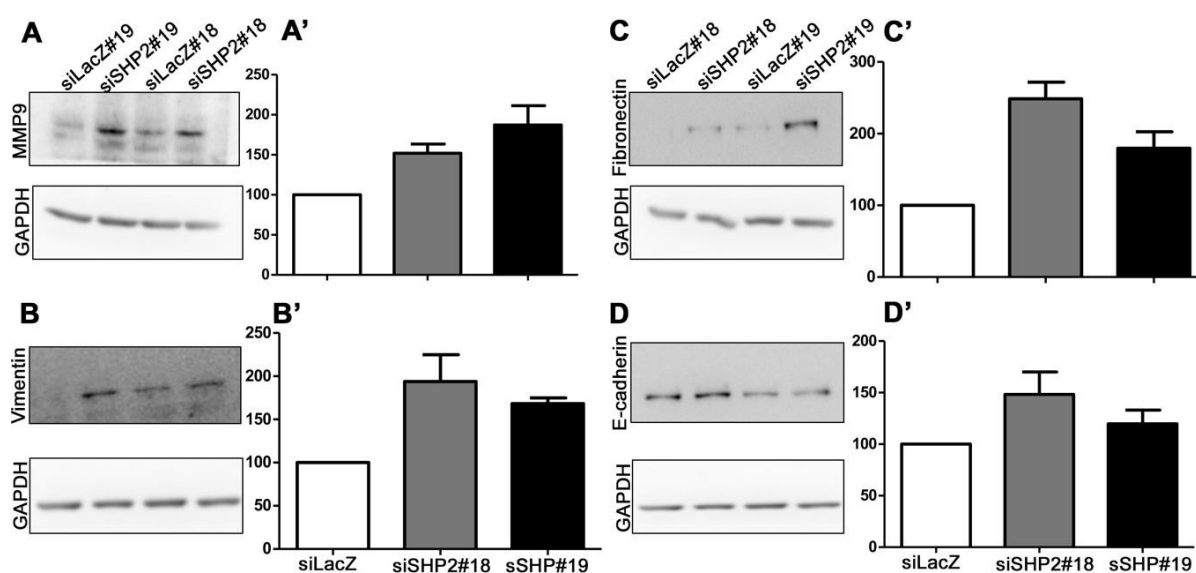

Figure 6: Knockdown of PTPN11/SHP2 enhances the expression of markers of epithelial to mesenchymal transition. Western blot analysis to examine the effect of the knockdown of PTPN11/SHP2 on the expression of MMP9, Vimentin, Fibronectin, and E-cadherin in MCF10A cells. GAPDH was used as loading control. Quantitation of representative blots shows a near significant increase in expression of MMP9 (A), Vimentin (B), and fibronectin (C), but no change in epithelial marker like E-cadherin (D). There were no detectable N- Cadherin levels in both control and PTPN11/SHP2-depleted cells (data not shown).

Figure 7

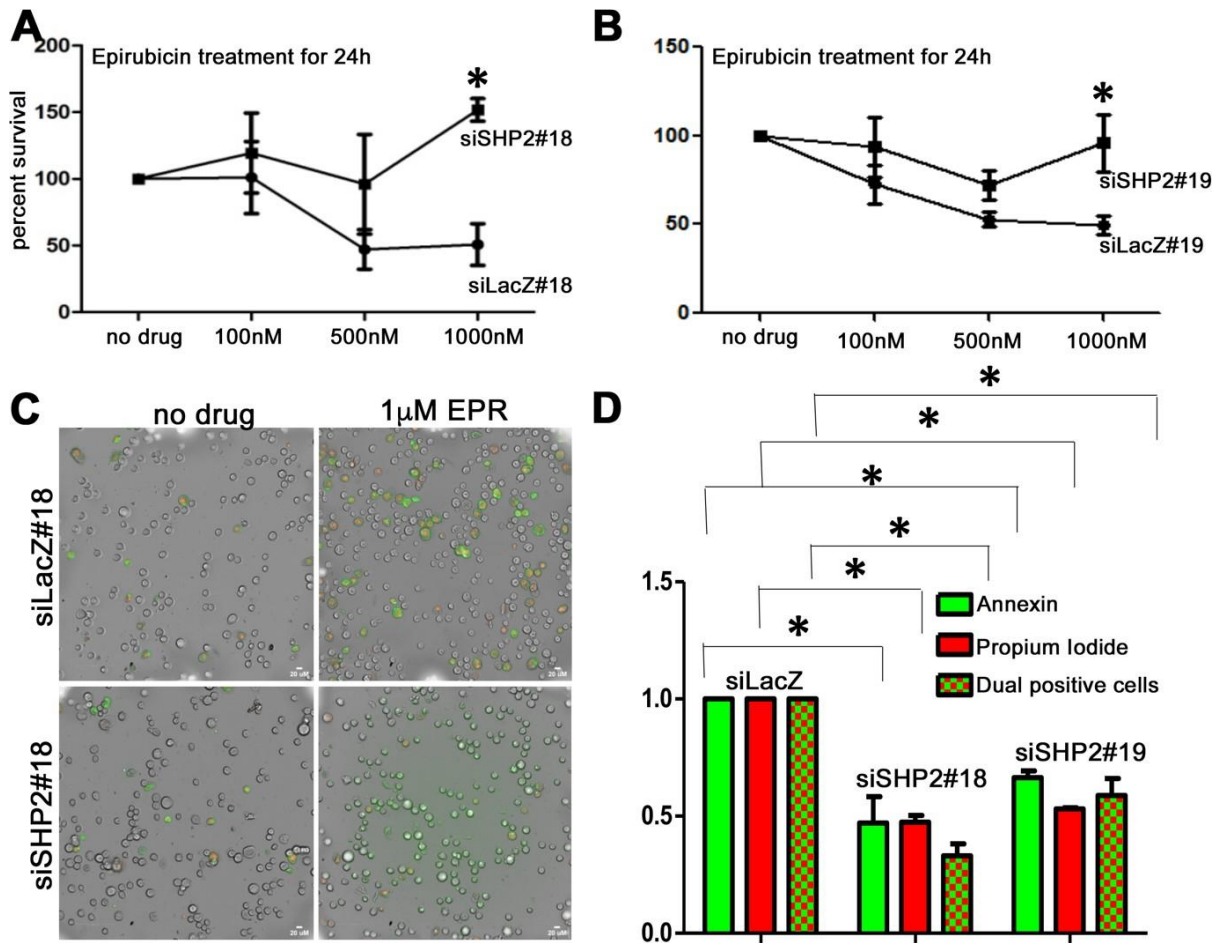

Figure 7: Knockdown of PTPN11/SHP2 reduces sensitivity to chemotherapeutic drugs in MCF10A cells. (A,B) MTT assay showing the dose-response curve upon epirubicin treatment in normal and PTPN11/SHP2-depleted MCF10A cells. We observed an increased survival advantage to PTPN11/SHP2-depleted cells at 1mM concentration of epirubicin. (C, D) Immunofluorescence images showing apoptosis in normal and PTPN11/SHP2-depleted MCF10A cells untreated and treated with 1mM concentration of epirubicin (C) and graphical representation of their quantitative differences (D). PTPN11/SHP2-depleted MCF10A cells show 2-fold decrease in Annexin positive, Annexin+ PI double-positive, and dead PI-positive cells.
